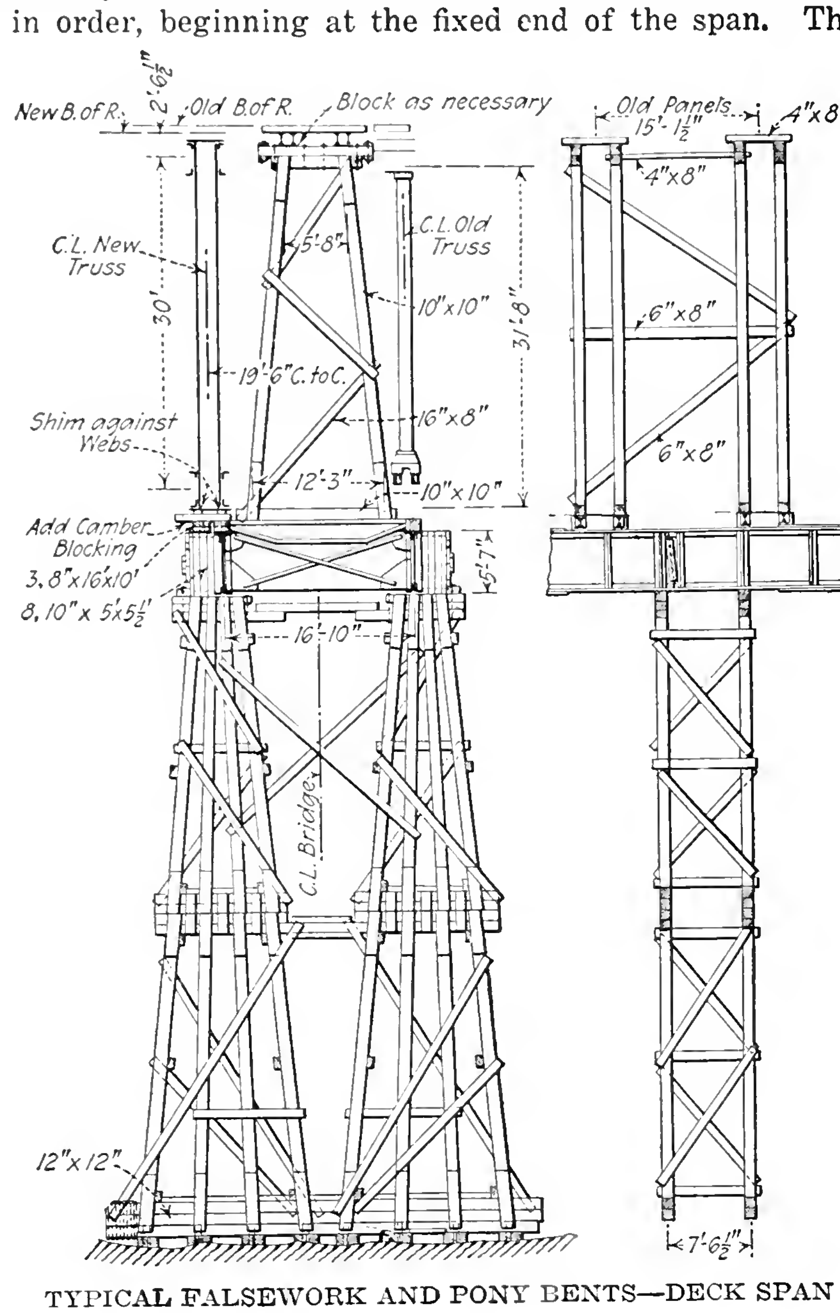
Regular Sequence Followed—Three spans at a time were thus carried on falsework, many of the bents of which were used over and over in successive spans, and a regular procedure was adopted, as follows: In the first span, the old wrought-iron members of the trusses were being burned through by acetylene torches and the cast-iron chord splice bolts burnt out, allowing the removal of the old trusses; in the next span the steel of the new trusses was in process of erection by a through mule traveler built up of steel and timber, as seen in one of the photographs; in the third span the new truss members were being riveted, and the falsework bents then removed for use in the next span.

Since the old trusses were so light, it was necessary to use care not to overload them in the erection operations carried out by derrick cars on the old tracks. In changing floor, two or three panel units were handled by these cars, the old stringer connections being cut through at the floor-beams. Special blocking on the pony bents supported the old stringers in adjacent panels.

Under the lift span, where the rock bottom of the canal is covered by several feet of soft mud, the bottom story of the falsework was set one leg at a time between guide timbers, and driven to bearing on rock by two or three blows of a light pile-hammer. This method was also used under the 644-ft. span, although the rock bottom was clear of mud. However, the depth of water, 10 or 12 ft., and the velocity of the current, about 10 miles per hour, would have made it very difficult to place concrete footings on the river bottom. Under the large span the legs were shod with cast-steel shoes, but no shoes were used in the canal. Before this scheme was adopted it was planned to use rock-filled cribs under the long span, but the attempt was abandoned.

Erecting 644-Foot Span—The general procedure in the erection of the 644-ft. span which replaced the old 400-ft. through span and one of the 245-ft. deck spans and involved, therefore, the removal of the intermediate pier, was as follows: A creeper traveler on the top chord of the through span was used in placing the timber bents below that span, and derrick cars placed the bents under the deck span. The spacing of these timber bents in the longer span was equal to the double-panel length of the big truss, while in the shorter span bents were placed under each panel point. Longitudinal steel girders were placed on top of these bents just below the lower chords of the main span in the longer opening, and below the lower chords of the deck span in the shorter opening. As illustrated in the cross-section here reproduced, these falsework bents supported the floor of the old bridge, two outside tracks upon which the material was transported and also the large gantry traveler which spanned the new trusses, the latter being spaced 34 ft. center to center. After supporting the old floor system, the old trusses were removed.

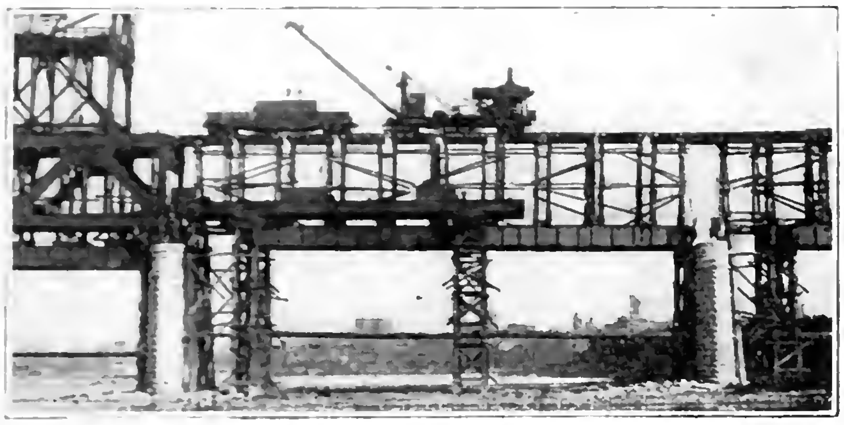
The gantry traveler which erected the heavy truss members was 145 ft. high overall, 124 ft. high inside and 46 ft. wide. This gantry traveler weighed 280 tons, with 100 tons extra weight for two engines. The lower chords of the trusses were placed first, then the floor system was changed, and the web members erected in order, beginning at the fixed end of the span. The



TYPICAL FALSEWORK AND PONY BENTS—DECK SPAN

heaviest members handled were the end posts and bottom chord sections, each of which weighs about 130 tons. The heaviest top chord weighs 95 tons and the heaviest diagonal 42 tons, the latter being about 95 ft. long.

Replacing the Top of Pier 19—At the Louisville end of the new long-channel span, it was necessary to increase the size of the supporting pier to carry the heavier load, and also to rebuild the top of the pier to provide a recess for the new deck truss span on the Louisville side, and at the same time secure adequate support for the heavy span. Futhermore, as the new span was erected before the adjacent 245-ft. old span had been supported by falsework, it was necessary to provide a special braced cross-girder to allow removal of the top of the pier and support the old span. The pier was enlarged by placing about 3 ft. of masonry around the old masonry, using stones removed from the top of the other piers, well anchored into the piers.



TRACK CARRIED BY PONY BENTS ON GIRDERS SUPPORTED BY TIMBER TOWERS

The top of this pier was first cut down to an elevation about 6 ft. below the bottom of the old truss pedestals, except that supporting stones immediately below the bearings were allowed to remain in place. The stones on the nose of the pier were then removed to about 39 ft. below the top of the pier, leveled off with 1 in. of cement grout to support the shoes of the temporary bent consisting of steel columns built up outside of the pier to carry the heavy temporary cross-girder already mentioned. Between trains, using old floor-beams for jacking beams, the end of the old span was jacked up, the stone pedestals below the bearings were removed, and the cross-girder was swung over to support the old span temporarily. The pier was then cut down to its final level, and steel grillages and new concrete coping were placed. In rebuilding the pier, old masonry was used as the outside facing, and concrete was placed for backing. For the support of the new deck truss span, it was necessary in the rebuilding of the pier to leave a recess carried back to the center line to allow for the end vertical posts and floor-beam of the 245-ft. deck span.

The grillages at the ends of the 644-ft. span were quite heavy; that for Pier 19 weighed 57 tons, being notched for the deck span, while that for Pier 21 weighed 73 tons, covering the full top of the pier. Grillages at the ends of the 370-ft. span weighed 50 tons.

Lift Span—The lift span replaces the old swing truss span and had to be placed with as little interruption as possible to either railroad or canal traffic. This was accomplished by first closing the old span, removing three panels at one end, and providing a temporary lift girder span in one channel. An 83-ft. clear opening between the timber bents was provided, these bents supporting the 90-ft. temporary girders. The operation of lifting the temporary girders to allow a boat to pass required about 20 min. and was carried out by the use of hand winches with wire lines to gallows frames at each end. The weight of this temporary span was 82 tons.

The steel-frame towers for the permanent lift span were erected and the old span was removed over both channels. Using a derrick car and locomotive crane the new floor and truss members were placed on falsework in the channel on the Louisville side of the canal. The floor and bottom chord were extended one panel, and the top chord two panels, north of the center of the span. This permitted the erection of the machinery house, situated on the top chord at the middle of the bridge, and the installation of practically all machinery, without the canal being closed. At the same time, the two north end posts were erected and the concrete counterweights poured and connected to the lift span. At this stage the canal traffic was of course closed while trusses were erected. Railroad traffic also had to be interrupted about eight hours while the temporary lift span was removed and the permanent floor placed. This operation was carried out by two derrick cars.

The plans for erection were developed under the general supervision of J. F. Ritter, superintendent of erection of the Bethlehem Steel Bridge Corporation, Steelton, Penn., with O. J. Marsten as assistant engineer in charge of drafting the plans, and J. L. Poffenburg as engineer in the field. J. J. Kelley was general foreman on the work. The plans for the erection were approved by J. C. Bland, engineer of bridges, Pennsylvania Lines West of Pittsburgh.

TEMPORARY LIFT GIRDER IN USE—HALF OF LIFT SPAN ON FALSEWORK

Power Flushers Economical at Ottawa, Ontario

Two power flushers mounted on motor trucks have satisfactorily flushed 18 miles of streets of various widths each day at Ottawa, Ont., according to the annual report of Andrew F. Macallum, commisioner of public works. The cost per mile averaged \$1.72. These trucks operated for 106 days at a cost of \$4650. They replaced 20 of the old horse-drawn sprinkling wagons at an operation cost of \$16,800. Thus a direct saving of \$12,150 is shown.

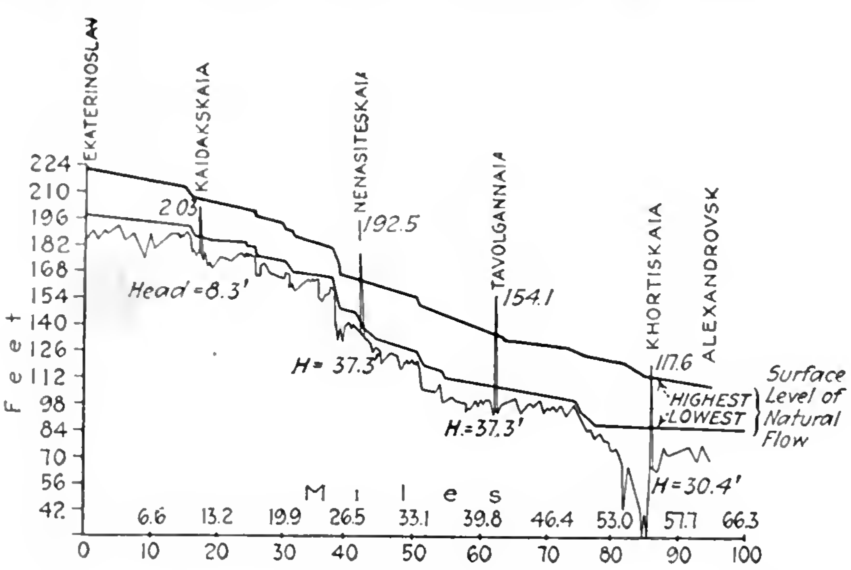
Russian Water-Power Possibilities at Dnieper River Rapids

Hydraulic and Canalization Project Interrupted by War — Four Dams and Power Plants Would Give About 600,000 Horsepower Nominal

By V. V. Tchikoff
Consulting Civil Engineer, Berkeley, Calif.

Water power is an important item in the vast natural resources of Russia. It will undoubtedly play a great part in the development of the country, because coal and other fuels are not distributed uniformly over Russia, and there is a lack of fuel in some very important industrial regions. The total potential water power of European Russia alone is estimated at 20,000,000 hp. or more. This is mostly concentrated in the border regions of Russia. The Caucasus has about 10,000,000 hp., and there are about 2,000,000 hp. in the north lake region. All the hydro-electric stations of European Russia have only some 250,000 hp., and most of them are small.

The rapids of the Dnieper River present one of the more interesting possibilities for early utilization. They are located between Ekaterinoslav and Alexandrovsk, within the navigable portion of the Dnieper River. They constitute one of the greatest obstacles to navigation on the canal system connecting the Baltic and the Black Seas. Beginning at Riga and ending at Kherson, this waterway will have a total length of about 1600 miles, utilizing the Rivers West Dvina and Dnieper.



PROFILE OF DNIEPER RIVER RAPIDS POWER SITES

The problem of utilizing the Dnieper River rapids has been worked out by many Russian and foreign engineers. The project of the Ministry of Way of Communication, in 1914, provided for the construction of four dams as follows (see profile): Kaidakskaia, with a fall of 8.3 ft.; Nenasiteskaia, 37.3 ft.; Tavolgannaia, 37.3 ft.; and Khortiskaia, 30.4 ft. The peculiarity of this project is the impounding of the night flow for use during the working hours of the day. Solid gravity dams were designed to be built on the granite foundation, and were to be provided with Thomas and Stoney gates. A canal with locks for boats of 7-ft. draft was proposed, with possibilities for 14-ft. draft.

The project was divided into two phases. The first phase was based upon the 37-year midsummer minimum discharge of 11,000 sec.-ft., corresponding to a turbine capacity of 238,600 hp. nominal, with a maximum of 316,800 hp. during the flood months of spring. The minimum discharge for a 15-day period is 15,100 second-feet.

For the second phase of the project there would be utilized about 22,000 sec.-ft., corresponding to a turbine capacity of 350,000 hp. nominal, and 465,000 maximum and a total of 588,600 hp. nominal. For this there would be necessary auxiliary steam plants of half the turbine capacity, working 90 days per year. The maximum capacity of the turbines was assumed as 1.33 times the nominal capacity. The construction cost of the dams, locks, etc., was estimated at about $25,000,000, and of the turbines, generators, etc., $16,500,000 for the first and $21,000,000 for the second phase, including the auxiliary steam plants, but not the transmission lines to Ekaterinoslav and Alexandrovsk, which are counted at $4,400,000.

For computation of the operation and maintenance costs per kilowatt, a working time of 3000 hours per year was assumed, and interest at 8% on construction capital. The resulting charges are shown in the accompanying table.

In computing the profit of all the stations for the first phase there was used an average operation and maintenance charge of 1.8 kopecks (0.9c.) per kilowatt-hour, well under the cost of power at which the steam plant can successfully compete. On this basis the profit for the first phase is estimated at $1,480,000, and for the second phase $1,700,000.

ESTIMATED CAPACITY AND COST OF DNIEPER RIVER WATER POWER PLANTS AND OPERATION AND MAINTENANCE COST PER KILOWATT-YEAR AND KILOWATT-HOUR

Name of Plant	Phases	Capacities of Turbines Hp. Nominal	Cost of Plants in Rubles, 1 Ruble = $0 515	Operation and Maintenance Cost Per Kilowatt-Year, Dollars	Operation and Maintenance Cost Per Kilowatt-Hour, Cents
Nenasiteskaia..	First	98,000	10,458,000	13.4	0.45
	Second	140,000	13,187,000	12.1	0.40
Tavolgannaia....	First	98,000	11,404,000	14.4	0.48
	Second	140,000	14,142,000	12.8	0.43
Khortiskaia	First	30,000	5,869,000	24.2	0.80
	Second	50,000	7,322,000	18.5	0.62
Kaidakskaia	First	12,600	4,087,000	38.2	1.27
	Second	20,000		--	....

A syndicate of French and Russian capitalists was ready to carry out the whole scheme of the Baltic-Black Seas waterway, but the old Russian Government was not willing to grant the concession and the Russian Duma was about to make an appropriation for the construction of the project when the great European war broke out.

Vandyke, Photostat and Blueprinting Costs

Production costs of vandykes, photostats and blueprints by the engineering division of the United States Ordnance Department, which during September, 1918, made 370,614, show a large reduction below commercial practice, according to the *American Machinist*. While the cost of vandykes and photostats varies with their size, an approximate cost per square foot can be given on vandykes 18 x 24 in., which cost 11½c. each and photostats 14 x 18 in., which cost 7½c. each. Upon this basis the costs per square foot were, vandykes 3.8c., photostats 4.3c. and blueprints 2 cents.

Excessive Storms Observed by the United States Weather Bureau

By Charles W. Sherman
Of Metcalf & Eddy, Consulting Engineers, Boston, Mass.

THE accompanying table shows the rates of precipitation of the most noteworthy storms which have been observed at Weather Bureau stations during 1901 to 1918, inclusive, as reported in the annual reports of the Chief of the Weather Bureau and in the *Monthly Weather Review*.

The data presented show the most intense storms anywhere in the United States at Weather Bureau stations,

and have been compiled with the idea of including, as a rule, not more than six storms in any one year. As is well known, the records of excessive storms, as published, are in the form of cumulative amounts for 5-min. intervals from the beginning of the intense precipitation. It has been necessary, therefore, to pick out a large number of storms which appeared on inspection to be most likely to include excessive rates of precipitation, and then compute the rates of precipitation corresponding to the reported amounts. The resulting figures for a large percentage of the storms were then rejected so as to leave only the most important of those in which the rate at some part of the storm was notably excessive. No storm was reported in 1902 which comes within the classification adopted for this tabulation.

With comparatively few exceptions, storms have not been included unless they showed rates of precipitation approximately as large as the following:

For 5 minutes	6.5 in. per hour
For 15 minutes	5 in. per hour
For 30 minutes	4 in. per hour
For 45 minutes	3.50 in. per hour
For 60 minutes	2.75 in. per hour
For 120 minutes	2 in. per hour

These data were worked up in the office of Metcalf & Eddy and are submitted for publication that they may be available for general use.

FIG. 2. ARMORY AS RECONSTRUCTED; BASE OF OLD FRONT WALL IN FOREGROUND SHOWS EXTENT OF SETTLEMENT AT RIGHT END

Faulty Foundation Causes Serious Damage to Armory

Settlement of Piles in Soft Subsoil—Attempts To Arrest Subsidence Fail—Part of Building Taken Down

INSUFFICIENT study of underground conditions resulted in so seriously defective foundation construction in the case of a Minneapolis armory that progressive settlement practically wrecked the building, and the only recourse was to take down part of it. The foundation piles under the building rested in a bed of soft mud instead of going down to a firm bearing stratum, and under the load of the building they went down, at some points as much as 2½ ft. In the course of some years much repairing was done and some attempts were made to remedy the defects. No method of underpinning the structure at reasonable cost was found, however, and finally the armory was condemned; as a temporary expedient, for war service, its heaviest portion was torn down and the drill hall kept in use.

The original structure (Fig. 1) was erected in 1905; its main part is sketched in the plan, Fig. 3. At the east end (left-hand of the view, Fig. 1) there was a rifle range about 20 ft. wide, while at the west end there was a driveway which was later replaced by a riding hall (at right in Fig. 2). The rear portion consisted of a drill hall, 120 x 174 ft., with a reinforced-concrete floor supported on concrete columns, and a steel arch-truss roof. The front part of the building was three stories high, and the floors were of reinforced concrete. The third floor, forming a 70 x 109-ft. dance hall, was roofed by 70-ft. steel arch trusses extending from the front wall to the forward truss of the drill hall. In 1912 a one-story riding hall, having a frontage of 163 feet and extending the full depth of the old building, was built on the west side of the armory. All contracts were let and the structure was supervised by the Board of Armory Commissioners, while the city building-inspection department had no connection with it.

Although the location was formerly swampy ground, and subsequent exploration showed that soft ground below a surface fill extended to a depth of over 40 ft., there seems to have been little or no study of foundation conditions before construction. Piling was provided, but it turned out to be entirely inadequate. Some years previously, in connection with the development of the surrounding high ground as a residence district, a fill of sand and gravel had been deposited over the soft ground, and this superficial condition may have misled the designers of the building. The original piles were 30 to 40 ft. long, as nearly as could be ascertained subsequently. One member of the piledriver crew is reported as saying that some of the piles went down

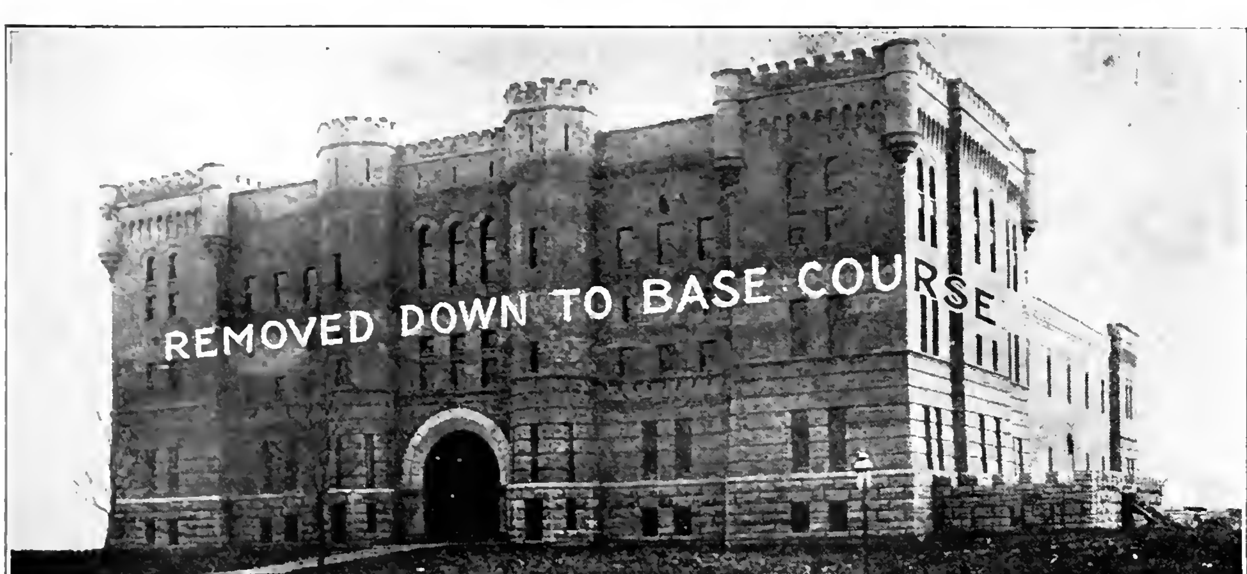

FIG. 1. THE ORIGINAL ARMORY; CONTINUED SETTLEMENT LED TO TAKING DOWN ENTIRE FRONT SECTION

12 to 24 in. under the last blow of the hammer.

Settlement developed even during construction. An attempt was made to level the floors by pouring on concrete, as noted in an account of the wrecking operations printed in *Engineering News-Record* of April 3, 1919, p. 687. Subsequent settlement was of such character that in 1913 the west wall of the main three-story building was condemned, torn down and rebuilt. An attempt to raise the building by jacks, to allow of constructing proper foundations, was made in the winter of 1916-17 by a house-moving company, but the jacks merely pressed their supports into the ground. The plan is reported as having been decided upon by the armory commissioners, without engineering advice. This work was abandoned, the blocking and jacks being left in place, as it was considered dangerous to remove them.

As long as the building continued in use it was necessary to screw up the interior jacks at intervals, in order to keep the floors level. After the building was closed by order of the building inspector, this work was not necessary, which tends to show that occupancy caused the local settlement.

The same contractor undertook to locate firm ground by sinking a well or open caisson about 8 ft. square, but at a depth of about 42 ft. the water rushed in to such an extent that this work was abandoned. Early in 1917 the city building inspector condemned the building as unsafe for occupancy, and it was closed.

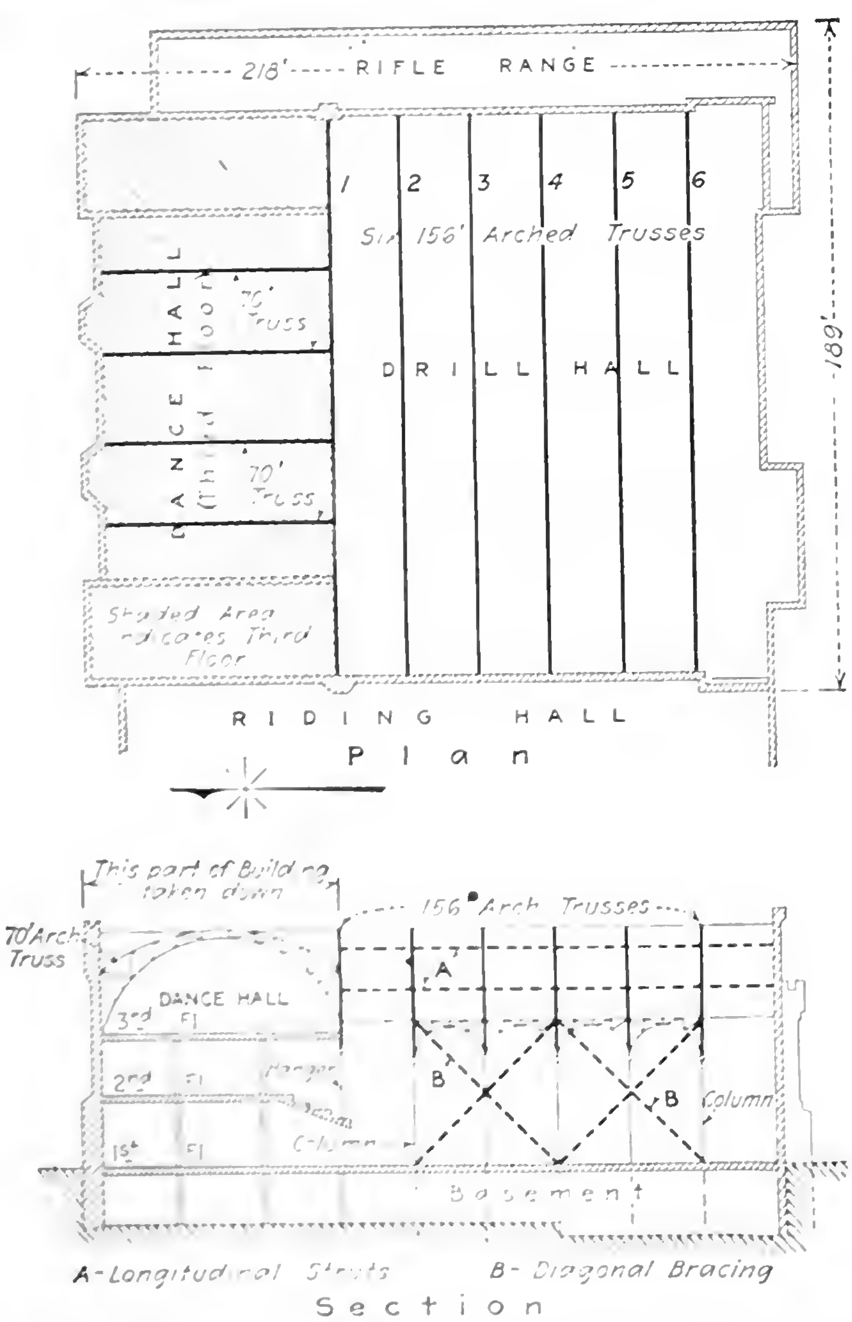

FIG. 3. ARMORY DAMAGED AND PARTLY TORN DOWN AS RESULT OF FOUNDATION FAILURE

In the summer of 1917, the city council requested F. W. Cappelen, city engineer, to make a thorough investigation of the matter and report to the Board of Armory Commissioners. Mr. Cappelen put down eight test holes from 70 ft. to 90 ft. in depth around the outside of the building, and one test hole inside of the building very close to the foundation for the west end of the main truss which carries a part of the roof as well as the third floor of the main building. He found that generally there was from 15 ft. to 20 ft. of surface fill, below which was a stratum of mud varying in thickness from a few inches to 41 ft. Underlying the mud were sand and gravel strata. Ground-water was about 1½ ft. below the footings, or below the cut-off level of the piles.

As to settlement, he found this to be 37½ in. at the northwest corner, 3 in. at the southwest, ½ in. at the northeast and zero at the southeast corner. The west ends of the roof trusses of the drill hall had settled 5 in. for the south truss and 9, 12½, 18, 21½ and 26 in. for the others, in succession. Their east ends had settled from zero to 2 in. Mr. Cappelen's report stated the conditions as follows: "Most of the inside columns and practically all the walls have settled. In fact, the whole building is wrecked, and the only reason that it does not fall down is that the concrete floors are reinforced and tie the whole thing together like a box."

Additional piles would have had to be 70 ft. or 80 ft. long and it would have been extremely difficult to put them down under the interior, while they would not be assured of proper lateral support owing to the great depth of the mud bed. The pneumatic system was considered to be out of the question. Adequate foundations would be prohibitive in cost, and even if they were built the structure itself would still be in a wrecked and unsatisfactory condition. For this reason Mr. Cappelen advised the Board of Armory Commissioners to remove the building, salvaging the trusses and material and perhaps leaving the riding hall, as the settlement here was light.

Owing to urgent need for the building for war services, however, the Board of Armory Commissioners felt justified in going to considerable expense to make it fit for temporary use, and a committee of engineers, architects and builders was appointed to investigate the matter further. This committee reported in March, 1918, that in the foundations of some of the walls and interior footings the piles were not only inadequate in number but did not reach the underlying stratum of sand. At other places the piles did penetrate the stratum sufficiently to make it certain that further settlement would be slow and might decrease. The committee recommended the removal of the three-story portion of the main building, and also of the adjacent main steel truss of the drill hall, as this latter would be left without lateral support, and had settled over 2 ft. at the west end. This was concurred in by Mr. Cappelen, in a report to the city council.

Alterations carried out to reinforce the high, arched roof of the drill hall included placing four lines of longitudinal struts connecting the trusses, and longitudinal diagonal bracing between the steel columns supporting these trusses, as shown on the drawing. The first-floor slab was left intact, as it ties the whole structure together. The floor was leveled from the old slab. Temporary walls of frame and stucco were built to inclose

the parts left open and to give a reasonably good appearance. The building as thus altered has been in use since October, 1918.

When this work was practically completed Mr. Cappelen found that the wrecking had not been done as suggested by the committee and concurred in by him, but that the heavy main truss had been left in place. Having no connection with the work, he simply reported the fact to the city council, so as to be on record in case anything should develop in the future. The steel trusses are said to show no signs of distress, in spite of the settlement of their supports.

Brick Chimney Carried On Platform At Roof Of Building

Concrete Slab Footing Is Supported From Ground By Separate Columns—Chimney Has Unusual High Taper

By J. G. Mingle

The Rust Engineering Company, Cleveland, Ohio

TWO features distinguish the brick chimney, illustrated herewith, recently completed for the power house of the Cleveland Electric Illuminating Co.; one is the large bottom diameter and consequent taper, the other is the method of support at the roof of the building.

The chimney, which is of the perforated radial brick type, is built on top of the power house and is supported by a reinforced-concrete and steel platform on top of 12 fabricated steel columns extending down through the building and resting on separate grillages. The top of the platform is approximately 105 ft. above the basement-floor level. The peculiar shape and great taper of the structure are due to the flue opening in the concrete platform which is 10 ft. wide and 37 ft. long, around and over which the chimney is built.

The height of the chimbney is 163 ft. above the top of the platform; the inside diameter at the top is 20 ft. and the outside diameter at the base is 43 ft. The radial brick wall is 20 in. thick at the bottom and decreases by sections, with an average decrement of 1 in. per 16 ft., to 10 in. at the top. The taper of the chimney varies from 0.016 ft. per foot for the top section to 0.240 ft. per foot for the bottom section.

Reinforcement is provided both vertically and circumferentially, to resist any tensile stresses which may occur. The circumferential reinforcement consists of 4 x $\frac{5}{16}$-in. bands of strap steel bolted together in sections and embedded in the brickwork at vertical intervals of from 20 ft. at the top to 5 ft. at the bottom.

The vertical reinforcement consists of $\frac{3}{4}$-in. twisted square rods spaced on approximately 5-ft. centers and also embedded in the brickwork. The chimney is lined on the inside with perforated radial brick to a height of 26 ft. The lining is so arranged that it serves the double purpose of protecting the outside wall and preventing the soot from collecting on top of the platform. The brickwork is laid up in 2 cement, 3 lime and 5 sand mortar. It was necessary to make the mortar fairly stiff to keep the brick from slipping when they were being laid up. The brick are red in color. The chimney is designed to withstand a wind of 100 miles per hour with no tension at the windward side and a maximum compression of 15 tons per square foot at the leeward side. The weight of the entire chimney, including the lining, is approximately 1200 tons. It was designed and built by the Rust Engineering Co., of Pittsburgh, Penn.

HIGH AND WIDE BRICK CHIMNEY CARRIED ON STEEL COLUMNS REACHING CLEAR TO GROUND

Effect of War on Manganese Ore Industry

Prior to the European war the United States produced less than 1 per cent of its manganese requirements. The remainder was imported mainly from India, Russia and Brazil in the form of ore, and from Great Britian in the form of ferromanganese. It is noted that the countries possessing the largest and richest deposits have an abundant and cheap labor supply. Under war conditions India and Russia were practically eliminated as sources of supply. The productive capacity of the world's major deposits is much greater than the total demand for ore for steel making. The industry considerably expanded in Brazil and in Cuba during the war period. The large supplies from these nearer countries, together with the increased domestic output, proved greater than even the enormously expanded needs of this country. The United States became independent of British ferromanganese and of Indian and Russian ore. Domestic production of high-grade (i.e., 35% or more manganese) ore, used largely for making ferromanganese, increased from 4063 tons in 1913 to about 294,000 tons in 1918. Production of low-grade (less than 35% manganese) ore, used partly for making spiegel and partly smelted direct in iron furnaces, increased from 85,588 tons in 1913 to over 1,079,000 tons in 1918.

General Solution of Problems in Railway Compound Curves

Fundamental Equations Are Derived and Applied to Several Usual Cases Encountered in Railway Practice—Shifting and Revolving of Tangents Considered

BY ANTONIO LLANO
Montclair, N. J.

General Equations and Problems

FOR THE solution of problems in compound circular curves connecting two tangents, previous writers have failed to use the valuable principle of generality and have sometimes complicated the subject by a false appearance of simplicity. Some general equations are here derived and discussed. These equations are applied to several of the common problems in railroad curves, arising especially in street-railway work. The problems of shifting a tangent parallel to itself and of turning a tangent about its tangent point are solved by shorter methods than those usually given in textbooks on the subject.

Referring to Fig. 1, let $t_1 = T_1C$ and $t_2 = CT_2$ be two tangents to be joined by a compound curve. The exterior angle of intersection is denoted by Δ, the chord

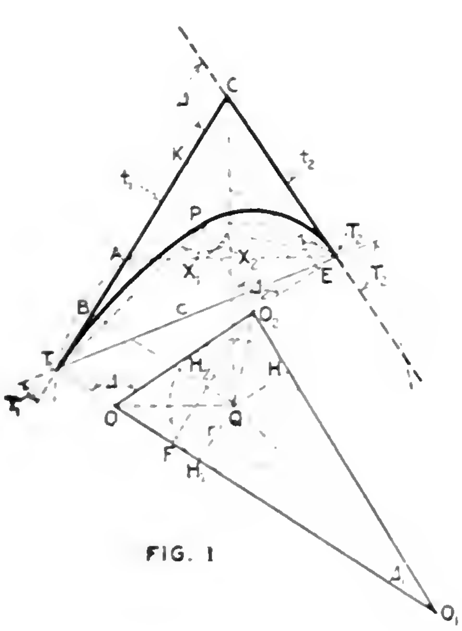

FIG. 1

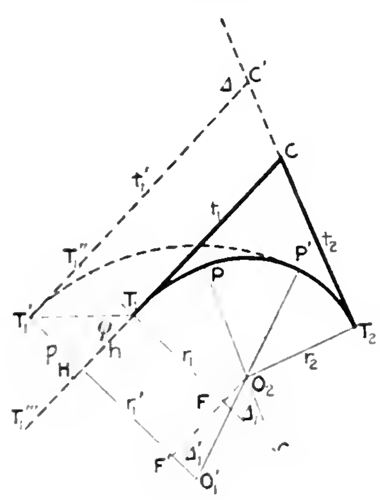

FIG. 2

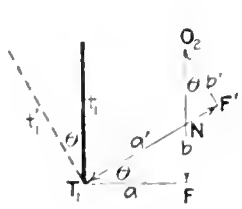

FIG. 3

FIG. 1. DIAGRAM SHOWING FUNDAMENTAL PROPERTIES OF COMPOUND CURVES. FIG. 2. SHIFTING A TANGENT TO A PARALLEL POSITION. FIG. 3. TURNING A TANGENT ABOUT ITS TANGENT POINT

T_1T_2 by c, and the angles between the chord and the tangents by T_1 and T_2, as shown. The heavy curve T_1PT_2 is one of the possible compound curves, P being the point of tangency of the two branches. The centers O_1 and O_2 of the branches T_1P and PT_2 lie in the normals T_1O and T_2O to t_1 and t_2, respectively, which meet at O. Since the angle T_1OT_2 is the supplement of the interior angle C, it is equal to Δ. The radii T_1O_1 and T_2O_2 will be denoted by r_1 and r_2, respectively, and the central angles by Δ_1 and Δ_2.

The determination of the locus of the variable point P is convenient both for the derivation of the general formulas and for the graphic solution and discussion of problems. Take $CA = CT_2$, and draw AT_2, PT_1 and PT_2. In the triangle OO_1O_2,

$$\Delta_1 + \Delta_2 = \Delta$$

Since the two triangles PO_1T_1 and PO_2T_2 are isosceles, $x_1 = 90° - \Delta_1/2$ and $x_2 = 90° - \Delta_2/2$, and therefore $T_1PT_2 = x_1 + x_2 = 180° - (\Delta_1 + \Delta_2)/2 = 180° - \Delta/2$. It follows that the locus of P is an arc described on c such that all angles inscribed in it shall be equal to $180° - \Delta/2$. The following is the simplest way of determining the center of that arc. In the triangle CAT_2, angle $CAT_2 = \Delta/2$, and also

$$T_1AT_2 = 180° - CAT_2 = 180° - \Delta/2.$$

Therefore, the required arc must pass through A; hence its center Q is the center of the circle circumscribed about the triangle AT_1T_2, and is at the intersection of the perpendicular bisectors BQ and CQ of AT_1 and AT_2, the perpendicular CQ being also the bisector of the interior angle at C. The arc is shown in dotted lines.

Although the arc just determined is the locus of *P*, not every line drawn from it cutting the two normals determines the centers of two circles fulfilling the conditions; for the line PO_2O_1 must fulfill another condition not involved in the mere fact that it cuts the normals and the arc. The line QO_2, being the line of centers of two circles meeting at P and T_2, bisects the angle Δ_2 made by the radii drawn from O_2 to the points of intersection. For a like reason, QO_1 bisects Δ_1. Therefore, Q is the point of intersection of the bisectors of the triangle OO_1O_2, and hence also the center of the circle inscribed in that triangle. The points of tangency of this circle with the three sides are denoted by H_1, H_2 and H, and the radius by r. From the figure,

$$r = QH_1 = BT_1 = AT_1/2 = (t_1 - t_2)/2$$

Any line tangent to the arc H_1HH_2 and bounded by the arc T_1AT_2 and the normal T_1O produced determines one value for each of the quantities r_1, r_2, Δ_1, Δ_2. It will be observed that only one of these quantities can be assumed at pleasure when t_1, t_2 and Δ are given.

Derivation of the Fundamental General Equations—As it is convenient sometimes to use the half angles, and sometimes the whole angles, two systems of equations will be derived.

Fig. 1 gives

$$T_1H_1 = BQ = BC \tan C/2 = \frac{t_1 + t_2}{2} \cot \Delta/2$$

Also,

$$T_1H_1 = r_1 - O_1H_1 = r_1 - \frac{t_1 - t_2}{2} \cot \Delta_1/2$$

Therefore

$$\frac{t_1 + t_2}{2} \cot \Delta/2 = r_1 - \frac{t_1 - t_2}{2} \cot \Delta_1/2 \qquad \text{(a)}$$

Interchanging t_1 and t_2, r_1 and r_2, Δ_1 and Δ_2:

$$\frac{t_1 + t_2}{2} \cot \Delta/2 = r_2 - \frac{t_2 - t_1}{2} \cot \Delta_2/2 \qquad \text{(b)}$$

Equations (a) and (b) can be transformed thus:

$$(t_1 + t_2) \cot \Delta/2 + (t_1 - t_2) \cot \Delta_1/2 = 2r_1 \qquad (A_1)$$

$$(t_1 + t_2) \cot \Delta/2 + (t_2 - t_1) \cot \Delta_2/2 = 2r_2 \qquad (A_2)$$

These are the fundamental half-angle equations. Together with the equation $\Delta_1 + \Delta_2 = \Delta$, they form a system of three independent equations by which any three of the quantities involved can be computed when

the others are known. As there are seven quantities, any four of them can be assumed at random, with the only limitation that Δ, Δ_1 and Δ_2 cannot all three be assumed, since they are connected by the relation just mentioned. This does not mean that any assumed values will lead to practical solutions; but the cases of impossibility will be indicated by the resulting equations themselves, as when a negative value is found for one of the radii or angles. Equations (A_1) and (A_2), when taken together, will be called system (A).

Whole-Angle Equations—The whole-angle equations can be derived by successive transformations of equations (A), but it is simpler to derive them directly from Fig. 1. Draw T_2K perpendicular to t_1 and EO_2F perpendicular to T_1O_1, and therefore parallel to t_1. The angle ET_2O_2 is equal to 180° — Δ (quadrilateral OK). Now

$$\begin{aligned} t_2 \sin \Delta &= KT_2 = KE + ET_2 \\ &= T_1F + r_2 \cos (180^\circ - \Delta) \\ &= r_1 - FO_1 - r_2 \cos \Delta \\ &= r_1 - (r_1 - r_2) \cos \Delta_1 - r_2 \cos \Delta \qquad \text{(c)} \end{aligned}$$

Interchanging subscripts:

$$t_1 \sin \Delta = r_2 - (r_2 - r_1) \cos \Delta_2 - r_1 \cos \Delta \qquad \text{(d)}$$

Writing (1 — vers) instead of cos, (d) and (c) take the following forms:

$$t_1 \sin \Delta = r_1 \text{ vers } \Delta + (r_2 - r_1) \text{ vers } \Delta_2 \qquad (B_1)$$
$$t_2 \sin \Delta = r_2 \text{ vers } \Delta + (r_1 - r_2) \text{ vers } \Delta_1 \qquad (B_2)$$

Sometimes the chord c and the angles T_1 and T_2 are given instead of t_1 and t_2. In that case equations (A) and (B) are transformed thus: From trigonometry,

$$t_1 - t_2 = \frac{c \sin(T_1 - T_2)/2}{\sin \Delta/2}$$

$$t_1 + t_2 = \frac{c \cos(T_1 - T_2)/2}{\cos \Delta/2}$$

Substituting in (A) and transforming:

$$c \sin \frac{T_1 - T_2}{2} [(\cot \Delta_1/2 + \cot(T_1 - T_2)/2] = 2r_1 \sin \Delta/2 \qquad (A'_1)$$

$$c \sin \frac{T_2 - T_1}{2} [(\cot \Delta_2/2 + \cot(T_2 - T_1)/2] = 2r_2 \sin \Delta/2 \qquad (A'_2)$$

The equations of system (B) are transformed by writing

$c \sin T_2/ \sin \Delta$ for t_1 and $c \sin T_1/ \sin \Delta$ for t_2,

which gives

$$c \sin T_2 = r_1 \text{ vers } \Delta + (r_2 - r_1) \text{ vers } \Delta_2 \qquad (B'_1)$$
$$c \sin T_1 = r_2 \text{ vers } \Delta + (r_1 - r_2) \text{ vers } \Delta_1 \qquad (B'_2)$$

The equations will now be applied to the solution of some of the usual problems.

(a) *Given the two tangents and their angle of intersection, and one of the radii (or the corresponding degree of curve), to compute the other radius and the central angles.*

Suppose r_1 to be given, to determine Δ_1, Δ_2 and r_2. Equation (A_1) at once gives

$$\cot \Delta_1/2 = \frac{2r_1 - (t_1 + t_2) \cot \Delta/2}{t_1 - t_2} \qquad (1)$$

Then, $\Delta_2 = \Delta - \Delta_1$, and r_2 is found from (A_2).

If c, T_1 and T_2 are given instead of t_1 and t_2, use the system (A′).

(b) *Given the lengths and degrees of curve of the two branches of a compound curve; or, what is the same thing, given r_1 and r_2, and the angles Δ_1 and Δ_2 ($= \Delta - \Delta_1$), to find the tangent points; that is, the tangent distances t_1 and t_2.*

As already stated, this problem is perhaps the most common. At first sight it may seem that equations (B), which at once give t_1 and t_2, are the better to use in this case. They are preferable for rough work, using natural functions; but for accurate work the equations (A) lead to simpler results, involving easier computation. The process consists in calculating $(t_1 + t_2)/2$ and $(t_1 - t_2)/2$ and then t_1 and t_2 by the equations

$$t_1 = (t_1 + t_2)/2 + (t_1 - t_2)/2 \qquad (2)$$
$$t_2 = (t_1 + t_2)/2 - (t_1 - t_2)/2 \qquad (3)$$

Subtracting (A_2) from (A_1):

$$(t_1 - t_2) (\cot \Delta_1/2 + \cot \Delta_2/2) = 2(r_1 - r_2)$$

whence, solving for $(t_1 - t_2)/2$ and replacing cot by cos/sin,

$$(t_1 - t_2)/2 = \frac{(r_1 - r_2) \sin \Delta_1/2 \sin \Delta_2/2}{\sin \Delta/2} \qquad (4)$$

Having computed $(t_1 - t_2)/2$, equation (A_1) gives

$$(t_1 + t_2)/2 = [r_1 - \frac{t_1 - t_2}{2} \cot \Delta_1/2] \tan \Delta/2 \qquad (5)$$

and t_1 and t_2 are found by equations (2) and (3).

(c) *Given one of the tangent points, the two radii and the angle Δ, to find the other tangent point and the central angles.*

Suppose t_1, Δ, r_1 and r_2 to be given, to find Δ_1, Δ_2, and t_2.

In this case the equations (A) are not convenient, and the equations (B) are used.

From (B_1):

$$\text{vers } \Delta_2 = \frac{r_1 \text{ vers } \Delta - t_1 \sin \Delta}{r_1 - r_2} \qquad (6)$$

Then, $\Delta_1 = \Delta - \Delta_2$, and ($B_2$) gives

$$t_2 = \frac{r_2 \text{ vers } \Delta + (r_1 - r_2) \text{ vers } \Delta_1}{\sin \Delta} \qquad (7)$$

For logarithmic work it is better to compute $t_1 - t_2$ by equation (4), after Δ_1 and Δ_2 have been found, and then t_2. One should not be deceived by the apparent simplicity of such expressions as the second member of (7). The arithmetical work involved is very laborious. The logarithmic work in (4), being more uniform and in a certain sense more mechanical, is much easier and safer.

It should be understood that the preceding formulas are entirely general. It is immaterial whether in them t_1 is greater or less than t_2, or which of the two tangents is called t_1 and which t_2. Furthermore, from every equation another similar equation can be obtained by interchanging the subscripts. It is thus that (A_2) is obtained from (A_1), and (B_2) from (B_1). The same remark applies to all the problems that follow. This fact is here emphasized because writers complicate the subject by making separate problems of special cases which, being included in the general equations, do not require independent treatment.

Shifting One Tangent Parallel to Itself

It is often necessary or convenient, after the elements of a compound curve have been calculated, to shift one of the tangents parallel to itself a given distance, leaving the position of the other tangent and the corresponding radius and point of tangency unaltered. Referring to Fig. 2, let T_1PT_2 be a given compound curve, the notation being as in Fig. 1. Let the tangent t_1 be shifted to the position t'_1, parallel to and distant p from t_1. Let $T'_1P'T_2$ be a new compound curve connecting t'_1 and t_2, the point T_2 and the radius r_2 remaining unchanged; O'_1 the center of the branch T'_1P', r'_1 the radius, and Δ'_1 the central angle.

Geometrically, the problem is to determine a circle that shall be tangent to the given circle O_2 and the given line t'_1. The problem would be indeterminate if t'_1 were not located with reference to O_2, and it is for this purpose that r and Δ_1 are utilized; that is, they determine the position of t'_1 with respect to O_2. For, drawing O_2FF' perpendicular to the normals T_1O_1 and $T'_1O'_1$ and producing O_1T_1 to T''_1 on t'_1, we have

$$FT_1'' = FT_1 + p$$
$$= r_1 - (r_1 - r_2)\cos\Delta_1 + p$$
$$= r_2 + (r_1 - r_2)\text{vers}\,\Delta_1 + p \qquad \text{(a)}$$

In order to locate T'_1 from T_1, it is necessary to know the distance $h = T_1H_1$. The variable elements to be introduced are therefore r'_1, Δ'_1 and h. There is a system of two independent equations by means of which any two of them can be determined when the other is known. Those equations will now be derived.

The figure gives

$$FT''_2 = F'T'_1 = r' - F'O'_1 = r'_1 - (r'_1 - r_2)\cos\Delta'_1$$
$$= r_2 + (r'_1 - r_2)\text{ vers }\Delta'_1$$

From this and (a) follows

$$(r'_1 - r_2)\text{ vers }\Delta'_1 = (r_1 - r_2)\text{ vers }\Delta_1 + p$$

We have also

$$h = FF' = O_2F' - O_2F$$
$$= (r'_1 - r_2)\sin\Delta'_1 - (r_1 - r_2)\sin\Delta_1$$

The fundamental system of equations is therefore

$$(r'_1 - r_2)\text{ vers }\Delta'_1 = (r_1 - r_2)\text{ vers }\Delta_1 + p \qquad (C_1)$$
$$(r'_1 - r_2)\sin\Delta'_1 = (r_1 - r_2)\sin\Delta_1 + h \qquad (C_2)$$

If the tangent to be shifted is t_2, interchange the subscripts. If the tangent is to be shifted inwards, make p negative. A negative value of h indicates that H_1 lies between T_1 and C. Conversely, if, when H_1 is given, it lies between T_1 and C, make h negative. It is unnecessary to treat all these cases independently. To locate T'_1 directly from T_1:

$$\tan\phi = p/h \text{ and } T_1T'_1 = p/\sin\phi$$

The three problems that may arise will be briefly considered, mainly to call attention to some special cases. In order to avoid confusion, the formulas applying to such cases will be numbered with prime numbers, lest they should be taken for general formulas.

(d) *Given Δ'_1, to find r'_1 and h. Solve* (C_1) for r_1', and then (C_2) for h.

If $\Delta'_1 = \Delta_1$, (C_1) gives

$$r'_1 = r_1 + p/\text{vers }\Delta_1 \qquad (1')$$

Substituting in (C_2), solving for h and transforming:

$$h = p\cot\Delta_1/2 \qquad (2')$$

It follows that

$$\phi = \Delta_1/2 \text{ and } T_1T' = p\,(\sin\Delta_1/2) \qquad (3')$$

(e) *Given r_1, to find Δ'_1 and h.* Solve (C_1) for Δ'_1, and then (C_2) for h

If $r'_1 = r_1$, (C_1) gives

$$\text{vers }\Delta' = \text{vers }\Delta_1 + \frac{h}{r_1 - r_2} \qquad (4')$$

From (C_1) and (C_2)

$$\frac{h}{p} = \frac{\sin\Delta'_1 - \sin\Delta_1}{\text{vers }\Delta'_1 - \text{vers }\Delta_1} = \frac{\sin\Delta'_1 - \sin\Delta_1}{\cos\Delta_1 - \cos\Delta'_1}$$
$$= \cot(\Delta_1 + \Delta'_1)/2$$

whence

$$h = p\cot(\Delta_1 + \Delta'_1)/2 \qquad (5')$$
$$\phi = (\Delta_1 + \Delta'_1)/2 \qquad (6')$$

(f) *Given h, to find Δ'_1 and r'_1.* Dividing equation (C_1) by (C_2),

$$\tan\Delta'_1/2 = \frac{(r_1 - r_2)\text{ vers }\Delta_1 + p}{(r_1 - r_2)\sin\Delta_1 + h} \qquad (8)$$

Now r'_1 is found by either (C_1) or (C_2).

If it is desired that the new tangent point should be on the same normal or radial line as before (at T_1''), $h = 0$, and (8) becomes

$$\tan\Delta'_1/2 = \tan\Delta_1/2 + \frac{p}{(r_1 - r_2)\sin\Delta_1} \qquad (7')$$

Also, from (C_2),

$$r'_1 = r_2 + \frac{(r_1 - r_2)\sin\Delta_1}{\sin\Delta'_1} \qquad (8')$$

(g) *Given a compound curve, to shift one of the tangent points along the same tangent, without changing the other tangent nor tangent point, nor the other radius.* Referring to Fig. 2, the problem is to shift T_1 to another point, as T'''_1 on the tangent CT_1, without changing t_2 nor r_2.

This problem, which occurs mainly in street railroad construction, is but a special case of that of shifting a tangent parallel to itself. The three cases that may occur are solved by making $p = 0$ in equations (C). The distance h is the distance $T_1T'''_1$ that the tangent point is shifted. System (C) can easily be reduced, in this case, to the following form, which expedites the solutions:

$$(r'_1 - r_2)\text{ vers }\Delta'_1 = (r_1 - r_2)\text{ vers }\Delta_1 \qquad (C'_1)$$
$$(r_1 - r_2)\text{ vers }\Delta_1\,(\cot\Delta'_1/2 - \cot\Delta_1/2) = h \qquad (C'_2)$$

Turning a Tangent About Its Tangent Point

Given a compound curve, to change it so that one of the tangents may be turned about its tangent point through a given angle without changing the other tangent nor the radius corresponding to the other tangent, nor either tangent point.

Referring to Fig. 3, where t_1 is the original tangent, O_2 the center of the r_2 curve, as in Fig. 2, and O_2F is perpendicular to the normal to t_1 at T_1, the problem is to turn t_1 through an angle θ to the position t'_1, and determine the elements r'_1 and Δ'_1 (not shown) so that the curve shall still begin (or end) at T_1, with O_2 and r_2 remaining unchanged. This problem occurs in connection with changes of alignment. Some writers solve it by the analytic geometry of conic sections. The following solution is simpler:

From Fig. 2 the following values are obtained for the distances denoted in Fig. 3 by a and b:

$$a = T_1F = r_1 - (r_1 - r_2)\cos\Delta_1$$
$$= r_2 + (r_1 - r_2)\text{ vers }\Delta_1 \qquad (9)$$
$$b = FO_2 = (r_1 - r_2)\sin\Delta_1 \qquad (10)$$

Fig. 3 gives

$$a' = b\sin\theta + a\cos\theta = (r_1 - r_2)\sin\theta\sin\Delta_1$$
$$+ r_1\cos\theta - (r_1 - r_2)\cos\theta\cos\Delta_1$$

that is

$$a' = r_1\cos\theta - (r_1 - r_2)\cos(\Delta_1 + \theta) \qquad (11)$$

Likewise

$$b' = b\cos\theta - a\sin\theta = (r_1 - r_2)\sin(\Delta_1 + \theta) - r_1\sin\theta \qquad (12)$$

Applying (9) and (10)) to the r'_1 curve, we have

$$(r'_1 - r_2)\text{ vers }\Delta'_1 = a' - r_2 \qquad (13)$$
$$(r'_1 - r_2)\sin\Delta'_1 = b' \qquad (14)$$

whence, by division

$$\tan\Delta'_1/2 = \frac{a' - r_2}{b'} = \frac{r_1\cos\theta - (r_1 - r_2)\cos(\Delta_1 + \theta) - r_2}{(r_1 - r_2)\sin(\Delta_1 + \theta) - r_1\sin\theta}$$

or, transforming,

$$\tan\Delta'_1/2 = \frac{(r_1 - r_2)\text{ vers }(\Delta_1 + \theta) - r_1\text{ vers }\theta}{(r_1 - r_2)\sin(\Delta_1 + \theta) - r_1\sin\theta} \qquad (15)$$

Now r'_1 can be found from (14) and (12).

If t_2 is the tangent to be turned, interchange the subscripts. If the tangent is turned inward, change the sign of θ.

How the Engineers of Iowa Got a Registration Law

Personal Study on the Ground, Backed by Coöperating Organizations and Individuals, Is Accountable for Success

By J. H. Dunlap

Secretary, Iowa Engineering Society; Associate Professor of Hydraulics and Sanitary Engineering, State University of Iowa

ORGANIZATION, analysis of past failures, a continuous, scientific study, by engineers on the ground, of each legislative delay, personal contact with the legislators, and coöperation by all engineering organizations and all engineers in the state, are responsible, in a prominent degree, for the success attained recently in Iowa in making the proposed registration bill a law. The favorable action of the General Assembly was based on the conviction impressed upon it that the time had now come when the public should be protected, so far as law may protect it, from incompetent and reckless engineers, as had already been done in the cases of physicians and lawyers. To show just how the work was done is the purpose of this article.

An analysis of past failures showed that there had been, first, a lack of general coöperation among the engineers of the state both in preparing the bill for presentation to the legislature and in backing the bill before the legislature, and, second, a lack of scientific management of the bill after it had been introduced in the legislature. This lack of scientific management was usually confined to the public hearing before the committee to which the bill had been referred. The chairmen of the committees on legislation have found it a task to bring despair, to get together three or four engineers who could talk intelligently and persuasively before a committee of legislators in regard to the benefits of an engineers' license bill.

Sample of Engineering Oratory

The customary speech of an engineer when called to his feet by the committee was very much as follows: "Gentlemen, I believe this bill is a good one. I am sorry to say that I have not had time to think up any speech and I don't think it is necessary." And then our engineering orator would resume his seat in much confusion of mind and body, and proceed to mop the perspiration from his brow. The result of such tactics was, justly, that the committee would almost invariably slate the bill for indefinite postponement. In other words, no scientific study was made of just how to create the right attitude toward the bill by each member of the committee, before the bill was voted on in the committee.

Having learned something from our habitual failures, we tried the following procedure—this time with success. In order to secure the widest coöperation among the engineers of the state, irrespective of their membership in the Iowa Engineering Society, it was decided to hold at Des Moines, June 8, 1918, a joint conference of all the engineers and engineering and architectural organizations of the state. As a result of this joint conference, a committee representing each one of these organizations was appointed, with C. H. Young, president of the Iowa Engineering Society, as chairman and the writer as secretary. This committee was instructed to draft an engineers' registration bill, to submit it to all the engineers and to all organizations that would be affected by the law, and then to call a second joint conference to discuss the proposed bill.

After a study of the bills which had been enacted or proposed recently, a bill was drafted which was modeled closely on the Florida law and on the law suggested by the Joint Committee of the national engineering societies Feb. 4, 1915. This first draft of the bill was submitted to an informal group of interested engineers, was criticized and then was rewritten. Copies of the bill were then sent to a mailing list, reaching, it was hoped, every engineer in the state. Accompanying the bill was a call to a second joint conference Jan. 25, 1919.

At this conference each section of the bill was thoroughly discussed, and in many cases amendments were made. After a session nearly six hours long the final draft of the bill was approved as amended. The motion then prevailed that a committee be appointed to prepare copies of the bill as amended, to have the bill examined from a legal point of view by the attorney provided by the office of the Attorney General for such purpose, and then to submit the bill in its final form to the legislature which was soon to assemble. The chairman of the conference, Mr. Young, appointed an executive committee of five members, an advisory committee of eight members, and a promotion committee of 31 members.

Senator Takes Charge of Bill

Senator J. D. Buser, becoming convinced of the good points of the bill, consented to take charge of it in the Senate. He introduced it Feb. 11, 1919. It was referred to the committee on roads and highways. It was later thought best to have the bill transferred to the committee on cities and towns, which was easily arranged. At the public hearing before this committee, a few interested engineers appeared and tried to enlighten the members of the committee in regard to the good points of the bill. As usual, however, the same result came to pass—namely, the bill was slated for indefinite postponement.

At this juncture it was decided to make a scientific study to decide exactly what was the trouble. Accordingly, two engineers were dispatched to Des Moines, Mar. 20, to study this problem with the same thoroughness that engineers are accustomed to give to problems of other kinds. From this point on, the most careful personal attention was given to each problem as it presented itself, with the result that the bill came out of the committee promptly and was passed by the Senate Mar. 26, with a few amendments, by a vote of 28 ayes, 16 nays, with six absent or not voting. Since the constitutional majority was 26, there were two votes to spare. Great credit for this successful result is due the engineers of the state who responded quickly to telegrams sent them two days before, asking them to get into personal touch with the senators from their districts.

Before the adjournment of the Senate for the day, it was learned that one of the senators had moved to reconsider the vote by which the bill had passed the Senate. By conference with him, it was learned that he wished to amend the bill so that private systems could be extended and constructed without the necessity of employing registered engineers, and also to amend the bill so that surveys, in all cases except where contests were involved, could be made by unregistered surveyors. Believing that it would be dangerous to have

the bill reconsidered on the floor of the Senate because of the small margin of safety in the vote, every effort was made to persuade the senator to withdraw his motion to reconsider. He finally consented to do so, when given a gentlemen's agreement that his desired amendments would be offered in the House.

In the House the bill was referred to the committee on municipal corporations. The progress of the bill in the committee was carefully watched by two engineers, assisted by such others as were available from time to time. The bill was reported out favorably by the committee just in time to be placed in the hands of the sifting committee, which had been appointed that very day to decide which bills, of the large number remaining to be acted upon, should be brought before the House. The problem presented by the sifting committee was carefully studied, since to lose at this point would have been to lose all. As a result, the bill was promptly reported out to the House, with the amendments proposed which had been agreed upon with the senator.

On Apr. 14 the bill was passed by the House by a vote of 81 ayes, 10 noes, and 17 absent or not voting. As the constitutional majority in the House was 55, the bill was declared to have passed the House.

The heavy vote in favor of the bill is a testimonial to the personal efforts of engineers in every county of the state in bringing the bill to the intelligent consideration of the representatives from their districts. It is impossible to place too much emphasis upon careful organization work of this kind. All such work should be reported back to those in personal charge of the work for the bill in the state house, in order that proper records and information may be instantly at hand when needed.

On Apr. 15 the Senate concurred in the House amendments with a vote of 35 ayes, no noes, and 15 absent or not voting. On Apr. 25 the bill was signed by the Governor.

Generous use of the telegraph and of the long-distance telephone, continuous scientific study, with characteristic engineering thoroughness, of each problem presented, and coöperation by all engineering organizations and all engineers in the state are responsible for the success of the bill. In personal conference with individual representatives it proved very helpful to have on hand a supply of brief abstracts of the bill, together with a brief list or arguments against the bill. The use of specific instances in which the bill, if it became law, would operate to prevent existing difficulties proved very effective. Many of the legislators seemed surprised when told that there was yet no law to prevent any one of them from hanging out his shingle and selling his services as an engineer anywhere in Iowa. When told, however, that he could not do this in Illinois, he usually concluded that Iowa should emulate her sister state.

Pennsylvania's Record Week in Road Letting

Reports from the Bureau of Public Roads, United States Department of Agriculture, indicate that Pennsylvania holds the record for amount of road work let in any one week. During the week ending Apr. 12 contracts were awarded for $2,034,378. This is considered an indication of the resources that will be enlisted in highway construction in this country in the near future. Of the contracts mentioned, the Federal Government will pay $911,407, under the Federal-aid act.

Cost of Operating Trucks on Highway Maintenance in Illinois

By B. H. Piepmeier

Maintenance Engineer, State Division of Highways, Springfield, Ill.

Details of the cost of operating five light trucks in maintenance work on Illinois highways are shown in the accompanying table giving figures for 1917 and 1918. The higher costs for the latter year are accounted for by the higher price of supplies and the greater age of the cars, two of which were new at the beginning of 1917. Trucks numbered 1, 3 and 5 are Ford cars converted into trucks; those numbered 2 and 4 are Ford-Smith Form-a-Trucks. All the trucks are subjected to very severe usage on account of the bad roads between jobs and the excessive loads they are compelled to carry at times. Annual depreciation on the cars is usually computed at about one-third their value, this figure being varied slightly each year to fit the general condition of the car upon completion of the season's work.

COST OF OPERATING ROAD-MAINTENANCE TRUCKS IN ILLINOIS

Truck No.	1	2	3	4	5
Type	Ford	Ford-Smith	Ford	Ford-Smith	Ford
Investment	$602.40	$795.53	$419.80	$784.54	$383.55
Figures for 1917					
Fixed charges per year:					
Interest	$20.33	$26.85	$14.17	$26.48	$12.94
License	4.00	4.00	4.00	4.00	4.00
Storage	38.20	124.73	20.00	25.60	67.55
*Total fixed charges	$62.53	$155.58	$38.17	$56.08	$84.49
Charges based on total mileage for year:					
Fuel and lubricants	$125.81	$210.39	$119.68	$182.92	$141.34
Mechanical repairs	72.01	73.40	76.91	148.08	76.25
Tires	82.45	12.75	75.45	28.00	119.53
Depreciation (computed)	279.63	325.72	152.63	399.31	220.16

Miles traveled	5,460	6,276	4,300	7,900	5,200
Cost, cents per mile	14.30	14.62	14.04	16.95	10.23

* Wages of chauffeur and insurance omitted.

British Concrete Colliers Have Precast Sides

Concrete colliers of a capacity of 1000 tons are being built for the British Admiralty by the firm of Christiani & Nielsen, of London. These boats are 185 ft. long, of 35-ft. beam and 18 ft. deep, and are novel on account of the method of casting the straight sides. The ships have a minimum of molded lines, a large proportion of the section being vertical straight sides with a flat bottom. The sides, which are composed of heavy vertical stringers and intermediate horizontal cross-beams, are cast horizontally on a flat platform, and after having attained their set are raised to the vertical position. Protruding rods are left for the bottom and deck. The curved bow and stern, being cast in place, have a shell 5 in. thick, as against the 3½-in. thickness for the precast sides.

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Engineers' Versus Laborers' Compensation

Sir—There is a curious letter in your issue of May 8, 1919, p. 931, from a young man, apparently 18 years of age, who received about $160 a month, including overtime, as a day laborer on an aviation field last summer, during the war, and whose spirit, in consequence, moves him to make invidious remarks about the opportunities for money-making offered by the engineering trade. He feels that it would be at least three years after graduation before a young engineer would receive a salary of $2000 a year. I feel that he is correct in feeling thus. He is rather dubious about the advisability of spending $1500 a year for four years in order to obtain an engineering education. I am rather dubious about the average young man obtaining the education if he spends the $1500. Most engineering students who spend this much become educated in matters quite interesting, perhaps, but not found in the school curriculums.

I would not have written this letter, however, were it not that the boy says he is dubious not only on account of the great wage he received as a laborer but on account of "similar conditions described by your readers." I have noticed these descriptions made quite frequently lately in letters to *Engineering News-Record*, and have wondered whether some of them might not have a serious effect upon some of your young readers who were thinking of becoming engineers. They evidently have had such effect upon, at least, one.

It is well, therefore, to iterate and reiterate the fact that an engineering education pays in money if in no other way. The laborer generally has to remain a laborer. The young graduate generally earns a fair salary at first—all he is worth, at first—and if he is able and continues to work very hard is sure to rise in his profession and be well paid. You will note I write only of payment in money, because the letters to your paper on this subject refer only to money—to the difference between the wages of laborers and the salaries of young engineers.

I certainly should be one of the last, for more than one reason, to criticize those who are trying to obtain better salaries for young engineers; but the cold fact remains that services, in the long run, receive the payment they are worth. The complaining letters are most frequently written by surveyors and draftsmen. The difficulty is that common surveying and ordinary drafting are not difficult to learn, and the law of supply and demand takes care of the pay for this kind of work. It is also a fact that a good carpenter is often worth more to a community than a good leveller or a good draftsman; but the opportunity of the leveller or draftsman to rise, if he has had a good education and works hard, is far better than that of the carpenter. It may be truly said of a young graduate of a good engineering school that he is self-supporting as soon as he begins his professional career and that, if he has average capacity and works hard, he need not let a laborer pass him in the running. Many presidents, managers and chief engineers of corporations, who have not written to *Engineering News-Record*, could substantiate this statement.

These remarks apply to other professions also, but the advantage in ours is that it costs less to obtain the necessary education and that young graduates become self-supporting much sooner than graduates of other professional schools; for instance, lawyers and physicians. And, in this age, it would be difficult to prove that even the later money rewards of lawyers and physicians average more than those of graduate engineers, so many of whom, as part owners or employees, have highly remunerative connections with large corporations.

PALMER C. RICKETTS,
President, Rensselaer Polytechnic Institute.
Troy, N. Y.

Sir—Reading the discussions in your journal about the compensation received by engineers never fails to interest me to a high degree. In your issue of May 8, 1919, p. 931, you print a letter by Lucien Alter, who apparently is very dubious about investing the necessary time and money to study engineering after comparing his earning capacity as a laborer with the earning capacity of his brother, a graduate of an engineering school.

Putting aside the fact that the high wages received by him are directly traceable to the urgency of war, I beg leave to ask Mr. Alter if his choice of a profession is solely guided by the expectation of making money.

If this is his predominant idea, I, as a graduate engineer who started work 25 years ago with the royal salary of $50 per month, would tell him very earnestly to divert his activities and energies into other channels. Such a frame of mind will surely prevent him becoming a real engineer—that is, a man who devotes his professional life to the creation of things useful to his fellow citizens and to mankind, and whose joy of life is derived from such work well done, irrespective of the size of the estate he may leave behind when he is called to the great beyond.

GUSTAV A. STIERLIN.
Pittsburgh, Penn.

Accidents and Expert Checking of Engineering Plans

Sir—Burtis S. Brown's interesting article, "Details of the Failure of a 90-Ft. Molasses Tank," and the editorial comment thereon, in your issue of May 15, have induced me to send you these few lines calling attention to a paper which I wrote for you nearly two years ago, and which was published in your issue of Nov. 22, 1917, p. 979, under the title "Why Not Have All Designs Checked by Outside Experts?" In that paper I advocated the checking of plans for all important engineering constructions, more especially those in which failure would jeopardize human life, and having such checking done by expert engineers who had not been concerned in the designing. Had such a precaution been taken in the case of the molasses tank no failure would have occurred, and 12 human lives would have been spared, to say nothing of the great damages to property which would have been avoided. The most simple calculations would have located the weakness; and it could have been corrected at comparatively small expense.

Another late example of fruitlessly expended money

through failure to check the working plans is that of the foundations on the Rondout Creek bridge, constructed under a former Commissioner of Highways for the State of New York. The amount of money there wasted was $48,000.

It would not be difficult to resurrect a long list of serious failures in engineering work which could readily have been avoided by proper checking of plans; but, as I stated in my original communication, "so doing would raise animosities and cause hard feelings, which is something to be avoided whenever possible."

Cannot you use the powerful influence of your paper to materialize this much-needed innovation in engineering practice? By doing so you would confer a lasting benefit upon both the engineering profession and the general public.

J. A. L. WADDELL,
Consulting Engineer.
New York City.

Military Training and the Army's Construction Work

Sir—Capt. R. K. Tomlin, Jr., has shown me an extract from his letter to you in regard to your editorial in the issue of Feb. 27, 1919, p. 408, entitled "Civilians Did Army's Construction Work in the United States." His purpose in writing you, and mine in the interview to which he refers, should be made clearer.

Without wishing in the slightest degree to detract from the credit due for the work of the Construction Division, I deprecate any tendency on your part to create, even indirectly, the impression that a knowledge of military procedure and familiarity with the essentials of military organization are not of great value in connection with such operations as were performed by the Construction Division, and of still greater value when the construction operations take place, as they did in France, in the actual theater of war, where the main and only satisfactory labor was that of soldiers.

As you doubtless know, construction work for the Army in the United States in peace is assigned to the Quartermaster Corps, while similar work in war in the theater of operations is assigned to the Corps of Engineers. Realizing the fact that war upon a modern scale would employ men, munitions, supplies and materials to an extent hitherto unknown, either in war or peace, and call for an enormous expansion of all our military facilities and personnel, with a correspondingly large program of construction operations, some time before our entrance into the war the Chief of Engineers in the United States, taking advantage of a newly made provision of law, sought to interest the engineers of our country in the Engineer Reserve Corps. His efforts met with a gratifyingly large response on the part of the profession, so that even before we entered into the war the Reserve Corps had a large personnel, including many of the leading engineers of the United States.

When our entry into the war became imminent, accelerated efforts were made to enlarge the Engineer Reserve Corps, and the ultimate result was that the number of engineer officers in our Army, which in the peace establishment amounted to something over 200, grew during the war to over 8000, most of whom were employed in France, although many were necessarily retained in the United States on work of supply, administration and organization. As many as possible of these engineer officers, so drawn from civil life, were sent to officers' training camps to become familiar with the fundamentals of Army discipline, organization and procedure, and everything possible was done to impart to the remaining officers who could not go to these training camps a similar knowledge.

These are the engineers who have officered our engineer combat organizations and who have executed the great work of construction in France, which in mere magnitude is at least equal to that done at home by the Construction Division, and which, in addition, has been executed under circumstances of far greater difficulty. To do this work in France it has been necessary to employ almost exclusively military organizations under the supervision of these engineer officers, so that practically the entire work has been that of men in uniform—soldiers, under close military control and discipline, whose operations were facilitated by the fact that those in authority over them were also soldiers, familiar with the necessity of military discipline and routine of administration.

This, then, is a point that I wish to emphasize—that certainly in the theater of war, where operations of construction must be performed by soldiers, it is of the highest importance that the engineers in charge shall be familiar with military procedure. In this manner alone can the work be conducted without undue friction and difficulty.

As the head of the engineer service of the American Expeditionary Forces, I have had a unique opportunity to come into contact with the leaders of our profession. Nothing that I can say would be adequate to express my admiration of the magnificent work that these men have done here in France, both in the combat organizations and in those more specially devoted to construction of various kinds. My experience with them has confirmed me in the belief that, professionally speaking, there is no real difference in training and attitude between the officers of the permanent Corps of Engineers and those of their professional brothers from the country at large who offered their services to the United States for the duration of the recent emergency. The education of officers of the permanent Corps of Engineers is conducted along sound engineering lines, and their normal experience in times of peace—namely, in the construction of works of seacoast fortification and of river and harbor improvement—involves the assembly, organization and use of the same instrumentalities as are employed by all engineers. Much of their work is done by force account, thereby adding breadth and value to their construction experience.

Feeling this to be true, it has been my deliberate policy here in France to make no distinction between those officers more recently drawn from civil life and the permanent engineer officers of the Army. I have endeavored to employ each man to the best national advantage, regardless of whether he came from civil life or from the Army. The results have proved that the country can, as it must, hereafter confidently rely upon the engineers of the United States, civilians, to furnish the large increase needed in time of war for the engineer work needed in the front line as well as along the line of communication; but, I am also convinced, it is a decided advantage to have these engineers enrolled in an Engineer Reserve Corps, the members of which are put in the closest possible touch with such details of military organization and administration as must exist in a well ordered Army. There must, of course, always be a corps of regular engineers, trained

and educated as indicated above, sufficiently large to take care of the necessary expansion, and to take charge of and prosecute all Government engineering and construction work in times of peace that may be confided to it.

In this way alone can proper coördination of effort and ultimate efficiency be secured, and it is to emphasize this important point that this letter is written. It would be, I think, extremely damaging to our country to permit the dissemination of a definite and widespread impression that for military purposes a civilian personnel, unfamiliar with and untrained in Army organization, administration and methods generally, is as serviceable as a force of corresponding productive capacity which has the added advantage of familiarity with necessary Army procedure.

W. C. LANGFITT,
Major General, U. S. A., Chief Engineer, A. E. F.
France.

Latin and Greek for Engineers

Sir—The article by Dean Cooley quoted in your issue of May 8, 1919, p. 930, touches a very live subject. There is no doubt that engineering graduates are narrow in their viewpoint. But are they the only ones? If my observation is to be trusted, the same criticism can be made of almost all men taking technical and even purely scientific courses. In other words, it applies to men whose work deals with *things* rather than with *persons*. Perhaps there is a tendency for this aloofness of attitude to be more pronounced with engineers, since so much of their work involves moving about, and hence they do not feel the same interest in their neighbors that a man would who felt more securely settled in his community.

If my idea is correct, the remedy is to turn more attention to subjects dealing with persons—history, sociology, economics, literature, English, modern languages. So far I go with Dean Cooley. But as for Greek and Latin—I doubt the benefit.

I am inclined to think there are few engineering schools where the other subjects mentioned above are not taught and some of them, at least, required. But the engineering students do not get the benefit that arts students do. And this is the crucial point, in my opinion. There is a constant effort on the part of engineering students to get out of the little that is required. The universal term for all such studies seems to be "junk," and if they cannot be escaped as little is absorbed as it is possible to do and get by. The arts student recognizes that this work is an essential part of his training and studies accordingly.

To remedy the situation we must make the student of engineering take the same attitude. It is extremely difficult for the college tc do it. The student regards the college authorities as prejudiced and as the victims of tradition. His home influences are very likely in the same direction; and I am of the opinion that the influence of many engineers is also. It will take many articles like that of Dean Cooley to counterbalance the remarks of Dr. Waddell on the study of Latin in the preface to "De Pontibus."

I hope it can be done. It will ease the path of the student adviser on the faculty. As it is, the man taking engineering wants engineering and nothing else, and the school must to a large extent meet his demand or lose the student. The acceptance of the obligation to train for good citizenship is connected with the acceptance of other obligations which are at variance with the popular philosophy that a man's prime duty is to get the most for himself and to ignore his duties to others.

I await with great interest further discussion of the article.

FRANK H. CLUTZ, PH. D.,
Department of Civil Engineering, Pennsylvania College.
Gettysburg, Penn.

Credit for Original Design of the New Orleans Army Base

Sir—A protest is in order on a matter of professional etiquette regarding the article on the New Orleans Army base in *Engineering News-Record* of Apr. 24, 1919, p. 823. This group of buildings was originally laid out, with no reference to its use as an Army base, by the engineers of the Board of Commissioners of the Port of New Orleans, and the layout was used almost without modification. The original reinforced-concrete design was made by C. A. P. Turner, of Minneapolis, and was in accord with the Chicago building code; this design was used with only minor changes involving additions to the cost of the structure. Two of these warehouses will be given back to the supervision of the Board of Port Commissioners, and payment of the cost of construction required. It is of course right and proper that the State of Louisiana should bear a part of the increased cost of construction made necessary by the assumption of this work by Army engineers with their appropriate demand for speed above all other considerations; but credit for the whole should not have been assumed without stating the above mentioned facts.

MARSHALL G. FINDLEY,
Designing Engineer, Board of Commissioners of the Port of New Orleans.
New Orleans, La.

[An inquiry regarding the facts recorded in the above letter addressed to George H. Davis, the author of the article in question, has been acknowledged by him as follows: EDITOR.]

Sir—I would acknowledge receipt of your letter, and note the communication which you have received from M. G. Findley making the point that the group of buildings was originally laid out, with no reference to its use as an Army base, by the engineers of the Board of Commissioners of the Port of New Orleans, and that the layout was used almost without modification. In reply I would say that on Aug. 15, 1918, you published an article on this development which included a perspective drawing showing the group of buildings in question and the New Orleans ship canal and terminal, as indicated, with accompanying maps and sketches. In this article it is mentioned on p. 306 that at the Mississippi River entrance of the canal commodity warehouses shown in perspective have just been started and have been taken over by the United States Government for use as quartermaster's stores. It is also mentioned at this point that the construction is being carried on under force account by the Board of Commissioners of the Port of New Orleans, of which W. B. Thompson is president and J. Devereux O'Reilly is chief engineer. On July 26, 1918, the firm of Ford, Bacon & Davis was appointed supervising engineers by the construction division of the Quartermaster Corps of the United States Army, and since that time the design and construction of the plant have been in charge of the

organization, as indicated by me in the article of Apr. 24, 1919, p. 826, to the exclusion of the Board of Commissioners of the Port of New Orleans or the engineers or other officers of the board. As to their previous connection, I am of the opinion that the article of Aug. 15, 1918, gave the Board of Commissioners of the Port of New Orleans and its engineers full publicity.

New Orleans, La. GEORGE H. DAVIS.

Definite Specification for Overhaul

Sir—The definition of "overhaul" and specification for payment are not easily made. The attempt described in your issue of Apr. 24, 1919, p. 835, is evidence sufficient.

The writer several years ago prepared the following definition and specification covering overhaul on canal earthwork. He believes it is readily understood by anyone familiar with this class of construction, and leaves no opportunity for misinterpretation.

"*Haul*—For all haul beyond the length of free haul overhaul shall be paid. The measure of overhaul shall be the 'station yard,' which shall be the hauling of one cubic yard one engineer's station, or 100 lin.ft. The amount of overhaul in any case shall be computed by determining the number of engineer's stations intervening between the center of mass of overhaul yardage as it lies in excavation and as it lies in embankment, deducting therefrom the length of free haul, in engineer's stations, and multiplying the remainder by the yardage of overhaul." EVERETT N. BRYAN.

Waterford, Calif.

Capital, Labor and the Engineer

Sir—In your issue of Apr. 24, 1919, p. 834, you print a letter from Thomas P. Morrissey in which he calls attention to the lack of understanding between labor and the professional engineer. He says the engineer "has seen fit to act as go-between" for capital and labor, and has "considered capital as his client."

In the first two ideas Mr. Morrissey is wrong. In the third he is right. At the beginning of work requiring engineering assistance the owner, generally the capitalist, starts an engineer on the work of preparing the plans. Thus, at the outset the engineer reaches an understanding with the capitalist. The engineer looks to the capitalist for employment, and not to labor. If the work requires execution the engineer is placed in charge and may then have some dealings with labor.

The engineer has never seen fit to act as go-between, and would not relish such a position, though he is sometimes half-way between. Capital and labor reach their agreements without the assistance of engineers. But the engineer often finds himself acting as buffer between two opposing forces. Sometimes these forces are a contractor and an owner, and sometimes they are a capitalist and a laboring class. From the nature of the engineering business this buffer position cannot be avoided.

On contract work which is done under the supervision of engineers, the engineers make the mistake of accepting employment direct from the owner. If the engineers would insist that the contractor have equal voice with the owner in the selection and payment of the engineer, there would be a certainty that the engineer would hold himself as much responsible to the one as to the other, and place himself above the suspicion of favoring any side of a transaction of which he is supposed to be an impartial judge. Build the Road to Fit the Traffic

Sir—Economy in highway transportation is far-reaching in its results, benefiting not only the users of the highway but the producers and the final recipients of the goods transported. For this basic reason, everything which, directly or indirectly, tends to lower the cost of highway transportation is of immediate interest to the public, which in the end pays the bills. The greatest economy in transportation can only be attained from a general application of systematic, continuous, organized effort directed along practical lines.

Such practical lines can only be determined by a complete recognition of all the factors involved in highway transportation and by a thorough study of their relations to one another and to the end sought. For such a study, much data must yet be secured and correlated.

One line of information needed for all the main traveled roads of this country is that of the kind, weight and amount of daily traffic passing over them. This traffic factor bears upon the selection of routes, establishment of grades, width of roadways, strength of bridges and culverts, type of pavement and cost of maintenance. A traffic census is needed *now*, before extensive and costly improvements are undertaken, in order that a more rational development may follow and the greatest economy be secured. The various highway commissions in this country could well devote some attention and funds to this important basic work and thereby lay the foundation for securing roads designed and built to fit the traffic. Every highway engineer, every highway commissioner, every good-roads advocate, every automobile and motor-truck association, every good-roads organization could well afford to adopt the slogan, "*Build the road to fit the traffic.*"

Kansas City, Mo. ROBERT C. BARNETT.

Wireless Telephone Outfits for Surveying and Construction Operations

Sir—The war witnessed the development of the wireless telephone from the experimental stage to that of a practical and usable field outfit. It has occurred to the writer that the portable wireless outfit, as used by the Signal Corps Field Service, U. S. A., will be a very useful adjunct to the equipment in many engineering operations.

The portable equipment consists only of two cases, containing the batteries and transmitting and receiving apparatus. The antennæ may be mounted on natural objects, or on two light 15-ft. poles included with the outfit, which serve as supports. These outfits usually have a range of from 5 to 20 miles. This equipment should prove useful to a water-works department, the engineer engaged in surveying, or to the construction engineer in conjunction with work covering considerable territory, such as construction of canals, pipe lines and railroads.

The writer once used six of these outfits in a survey

of base lines for triangulation in the Army meteorological and aërological work. Six different parties were distributed on this survey, and throughout the entire work were in constant communication with one another, although miles apart in rough and rugged country. The use of the wireless outfit so expedited the work in hand by permitting the six different parties to work in harmony with one another, when other means of visual signalling or wireless communication was impossible, that the survey, which otherwise would have taken a week or ten days, was finished in a single day.

Now that the war is over, these outfits will soon be on the market and engineers should not be slow in adapting them to civilian enterprises.

Albany, N. Y. FLOYD A. NAGLER.

Distortional Rotation and the Principle of Virtual Work

Sir—Referring to the article on finding the rotation of a member in a truss or at any point of a beam under stress, given in your issue of May 1, 1919, p. 864, it does not seem quite right to say that there is a new principle underlying the method presented. It was taught to the writer and its results pointed out, about 25 years ago, and in the last edition of "Modern Framed Structures" the problem is taken up and solved.

Aside from this, it seems to me that all similar questions about linear or angular elastic changes, as well as indeterminate stresses, are much more comprehensively treated by using the law of virtual work. Take for instance the bent beam, mentioned in the article:

If certain loads P and external moments M are applied to it and if, furthermore, any arbitrary deflections d are assumed to take place at the loads P and in the direction of the same, and any arbitrary rotations v at the external moments M, then the external virtual work done is:

$$\Sigma\, Pd + \Sigma\, Mv$$

This work shall now balance the work of the internal stresses. If the moment in any section caused by the loads P and the external moments M is called M_t and the moment in the same section corresponding to d and v is called M_s, the internal virtual work is

$$\int \frac{M_t\, M_s\, dx}{E\,I}$$

The equation

$$\Sigma\, Pd + \Sigma\, Mv = \int \frac{M_t\, M_s\, dx}{E\,I}$$

gives us immediately a means of finding either any rotation v or any deflection d. As P and M can be given any values we see fit to select, we may put every $P = O$, also every $M = O$ except at the point whose rotation is wanted, where we put $M = 1$ and get:

$$v = \int \frac{M_t'\, M_s\, dx}{E\,I}$$

By analogous assumptions we also get:

$$d = \int \frac{M_t''\, M_s\, dx}{E\,I}$$

The only difference is that M'_t in the first case represents the internal moment due to a unit external moment applied where v is wanted, and in the second case M''_t represents the internal moment due to a unit load where d is wanted. In either case M_s may represent the actual moment corresponding to v or d, as in your article.

It is apparent that if either M_t or M_s is equal to zero for any particular portion of the beam, the summation need not be extended over that portion, as it evidently does not have any effect on the elastic change.

Chicago, Ill. GEORGE N. LINDAY.

A Definition of Professional Engineering

Sir—The license committee of Engineering Council, in its study of laws adopted, or proposed, for licensing engineers in various states and in Canada, is considering one of the most puzzling details—to evolve a definition of professional engineering practice. The following definition has been arrived at after very careful study:

> The practice of professional engineering embraces designing and responsible supervision of the construction, operation or maintenance of private or public utilities or works, and designing or responsible supervision of processes of production, means of transportation and methods for the disposal of waste, when such designs or supervision involve and require the intelligent application of the principles of physics, mechanics, hydraulics or thermodynamics in the determination of the proper selection, use, removal or disposition of material for the attainment of a definite purpose.

The writer would be glad to have you print this definition and equally glad to receive from any of your readers comments or suggestions for its improvement, bearing in mind that brevity and clearness are all-important. Many of the definitions in the laws examined are very lengthy in detail, but, nevertheless, fail to define professional engineering adequately.

T. L. CONDRON,
Chairman License Committee, Engineering Council.
Chicago, Ill.

A Resource That Every Engineer Should Know

Sir—Let me recommend to all your readers that the headquarters of the American Library Association should be appealed to generally as a clearing house of information. If an engineer has a question that puzzles him and he does not live in a large city, with access to a good technical reference library, he should send his question to the American Library Association, 78 E. Washington St., Chicago.

Whether or not such appeal meets with due response, I should be glad to know the result, as I have long been working for a closer connection between the library industry and other industries. Experience with information bureaus has convinced me that there is great need to establish a public demand for information, for already there exist great facilities of which the public has hardly begun to avail itself. Moreover, my familiarity with the American Library Association enables me to say with confidence: Here is an organization having enormous research possibilities, which need only to be used in order to develop a large service that has long been latent.

I made the foregoing suggestion in a paper that was sent to a convention of chemists in Buffalo this spring, and so far three or four have acted upon it. The *Library Journal* for May published for me an article entitled "The Library Phalanx, a Presidential Address at a Phantom Convention." I believe this article would appeal to many who are interested in the general subject

of getting at information and to many who have been bewildered by the difficulties of getting as much out of a convention as they had hoped for. I shall be glad to send reprints of this article, upon request.

Subdrainage for Country Highways

Sir—Referring to W. P. Blair's article in *Engineering News-Record* of May 8, 1919, p. 914, and your editorial calling attention to some objections to subdrainage for highways: The writer has had many years' experience in planning and superintending drainage for highway, municipal and agricultural purposes, and has observed carefully the effect of subdrainage upon highways.

Many times, in constructing underdrains for agricultural purposes, farmers will take advantage of the highway side ditch in order to save depth in placing their outlets, often running some distance along the side of the highway. My observation has been, and the testimony of road superintendents is, that roadbeds where drains have been so placed settle much earlier in the spring and cost much less for maintenance.

A number of years ago, in constructing a gravel road, the writer placed a line of farm tile on each side, 8 ft. from the center line. In this case the outlets were not as good as they should have been, but the reports of the superintendent of roads show a much lower cost of maintenance than for similarly constructed roads without the drains. Residents along the line also state that this road settles and is ready for heavy traffic much earlier than the others.

The action of subdrainage is twofold: Removing excess water, and aëration of the soil.

This brings us to some objections mentioned in your editorial on the question of how to arrange for drainage of subsoils which are practically waterproof, such as clay. Where or when in the springtime did any contractor or engineer outside of arid regions find any clay that was not saturated with water? If it is waterlogged it must be porous; if there are pores the air can enter when the water is withdrawn. And therein lies the advantage of subdrainage. The removal of water from the subsoil permits the entrance of the air, and in flowing out, the water makes way for the small current of air which must flow in to take its place. This action places the soil in such condition that the moment excess moisture appears it begins to sink toward the tile instead of lying in the ground, which becomes saturated until the water is removed by evaporation. Subdrainage allows the grade to solidify much earlier and more quickly than when water stands in level side ditches and soaks into the grade. In cuts, subdrainage is especially advantageous, as it prevents ground water from the banks from reaching the subgrade.

Except in extreme cases, the writer would not regard the laterals shown in Mr. Blair's plan as necessary. In most soils the action of the subdrain will have its effect much farther than half the distance shown in his plan, and, when the subgrade is once drained and the hard surface road constructed, but little, if any, water will reach it.

Where highways are being reconstructed—that is, being changed from gravel or macadam to hard surface—through a well underdrained farming country, subdrains along the highway would be required in but few places.

As to the tile filling with roots, in the case of country highways this likelihood would be negligible, the occasional shade tree not being likely to have roots of the water-seeking variety, and, should such trees exist, the removal of the cause is a small matter.

The matter of subdrainage as an aid to maintenance is also neglected by the railroads, by which large sums could be saved by a small expenditure for such work. My experience has been that subdrainage is a benefit to any roadbed, making even the dirt road easier to maintain and better for travel.

M. H. DOWNEY.

Anderson, Ind.

[It should be noted that Mr. Downey has treated the problem largely from the standpoint of the rapidity with which saturated roadbeds dry out in the spring, rather than from the standpoint of maintaining dryness, which we understand to be the end sought by Mr. Blair. It is admitted that dry clay soil is hard to find in the spring. This is not only the case under earth and gravel roads, but also under hard surface roads. How to keep capillary water from collecting under the road surfacing and causing frost heavage in the winter is the problem to be met by the engineer. When the roadbed is saturated the damage is done. That roots are a problem in some sections, at least, is shown by inquiries that we receive as to how to prevent such clogging of the tile.—EDITOR.]

Suggestion for Geological Survey Maps

Sir—I learn from your editorial in the issue of Apr. 17 that an effort is being made to popularize the Geological Survey maps by making the contours more understandable to the general public through the use of colors.

I made an experiment of this kind a few months ago that may be of interest. I had a comparatively large map of a rough region in which a drainage project, a highway and a number of bridges were planned, which improvements it is proposed to finance by a municipal bond issue. For explaining the project to the public I desired to put the map in such form as would make the contours understandable to those unfamilar with such maps.

As the portion of the map desired to be brought out had a range of grades of 105 ft., represented by contours at 5 ft. intervals, 21 in all, I selected a complete spectrum chart of 21 shades of colors and had each of the contour lines colored to match one of the colors of the spectrum chart. I had the lowest grade colored a deep violet and each of the succeeding contours colored the successive spectrum shades, the highest contour line being red.

The resulting map brought out the differences in elevation in a remarkable way, except that the blue colors were largely lost, owing to the fact that the lines of the print itself were blue. If the colors had been put on a perfectly white paper and a slide of it made by the Lumière, or other color-photography process, it would probably have produced the effect desired.

The Geological Survey bureau probably has considered such a method, but if not may find it worth trying. Only when the maps are to be engraved, however, would it be possible to reproduce them without very great expense.

L. R. BOWEN,
Engineer of Bridges and Buildings, City of St. Louis.

St. Louis, Mo.

Hints for the Contractor

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Push Plow Unloads Flat-Cars

FOR unloading dirt from flat-cars a mechanical pusher or plow has been devised and built by the Denver Tramway Co. On a four-wheel truck is mounted the heel of a 55-ft. horizontal pole which carries a rectangular steel plate on the projecting end and is made rigid by means of three truss rods. On the rear end of the truck are piled old car wheels to form a counterweight.

This pusher stands on a siding at the dump. When a loaded car has been placed for unloading, the brakes are set and the side boards are lowered. The motor car then runs back and is coupled to the rear of the pusher car, which it drives forward until the plate on the pole has pushed the load off the floor of the flat-car. The brakeman stands behind the plate and guides it so that the entire floor of the car will be cleared.

In the description of this device by W. L. Whitlock in the *Electric Railway Journal* of May 10, 1919, p. 924,

PUSHER REMOVING SNOW FROM FLAT-CARS

it is stated that two men—conductor and brakeman—can unload a dirt car in about 15 min. In unloading snow, three men with the pusher were able to do the work of 15 shovelers, with an average of 6 min. per carload of 12 to 14 cu.yd. of snow.

Other Articles in This Issue of Interest to Contractors:

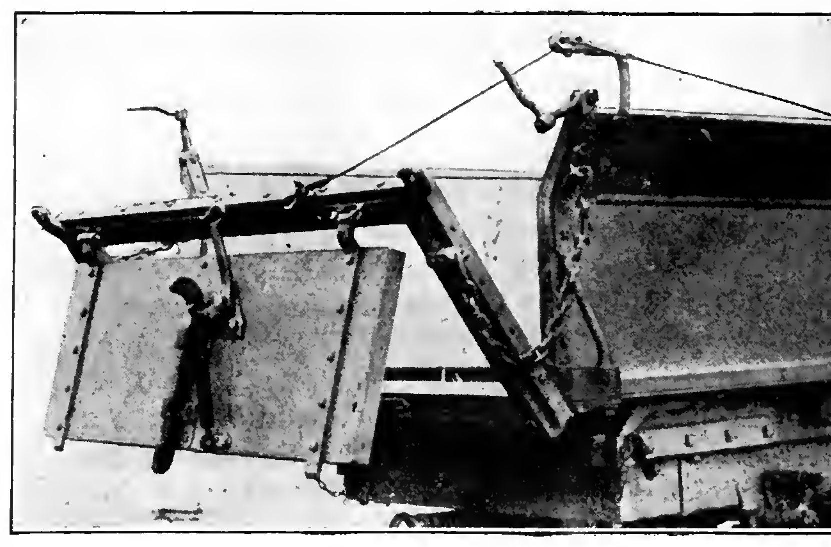
Gin-Pole Removes Train-Shed Trusses

REMOVAL of a steel train-shed roof without interference with traffic was carried out successfully by the Indianapolis Union Ry. in connection with the reconstruction of the union station. The framing consisted of trusses of 102-ft. and 68-ft. span, spaced 26 ft. to 45 ft. on centers and supported on steel columns. After the roofing had been stripped, each truss in turn was cut away near the ends by means of oxyhydrogen torches, the middle portion being handled by a gin-pole derrick having a 60-ft. pole guyed by cables and having its rope led to a hoisting engine placed on one of the platforms. As soon as the truss was cut and swung clear it was turned parallel with the tracks and lowered to the ground. This work had to be done in intervals between trains, and the method adopted eliminated the necessity of occupying the tracks by cranes or other machinery. The portable derrick could be quickly set up and guyed and as promptly removed to clear the tracks. The steel columns with the ends of the trusses attached were released from the footings and pulled over in a direction parallel with the tracks by men hauling on tackle hitched to the top of the column. The lowered trusses and columns were then loaded onto flat-cars by a railway wrecking crane and transported to their destination. By these methods interference with trains was entirely avoided.

Combination Detachable Truck-Body Serves Several Purposes

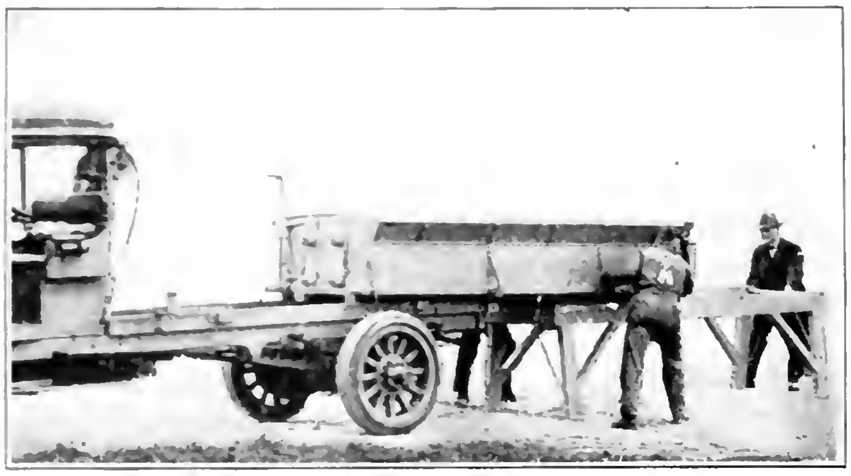
A MOTOR truck with a removable combination express and dump-delivery body has recently been delivered to Charles S. Wheeler of McCloud, Calif., by the Federal Motor-Truck Co. Express and other commodities can be hauled in the box, or sand, gravel, etc., can be hauled and dumped. The box being removed, heavy and cumbersome material such as logs, etc., can be hauled about Mr. Wheeler's estate.

The construction of the truck and the manner of manipulation are shown in the photographs. The tailboard is arranged with hinges at both top and bottom so that it will lie flat for loading merchandise, or open at the bottom for dumping sand and gravel. By releasing the hoist cables which are bolted to the front of the truck and removing the swivel bolts from the



DOUBLE-HINGED END BOARD LIES FLAT OR DUMPS

box hinges at the back, two men can roll the body from the truck frame, which is equipped with rollers, to the roller platform, as shown. This operation takes less than 4 min. The rollers on the frame are also advantageous for loading heavy material when the truck is used without the box. The hoist cables are arranged for drawing heavy materials upon the frame. The truck was especially designed to meet the requirements of Mr. Wheeler.



REMOVING BOX FROM ROLLER FRAME TO PLATFORM

Subaqueous Tunnel Heading Under Eight Inches of Rock Cover

By Alexander Lyle
Field Engineer, Booth & Flinn, Ltd., New York City

BY CAREFUL judgment in blasting, an interesting and difficult piece of tunneling was recently carried out successfully in one of the west headings of the new 14th St. rapid-transit tunnel under the East River, New York City. When the heading, which was advancing in full-rock face, without compressed air, approached a depression in the surface of the rock, the test holes that are drilled before each shot indicated that the rock cover was becoming exceedingly thin. Ultimately the rock proved to be only 8 in. thick over the top of the arch, at the lowest point of the depression. The question was how to proceed with the rock work under these conditions.

Here was a free-air rock tunnel 17 ft. 2 in. in diameter, with the roof to be trimmed to within 8 in. of the rock surface. The risk involved was that the river bottom might be brought in if the thin shell of rock were broken through. The material at this point was a good, homogeneous gneiss, overlaid by about 56 ft. of soft river-bottom material. The roof of the tunnel was 83 ft. below mean high-water level

In order that work should not be delayed by this thin spot, the top heading was dropped about 4 ft. and driven ahead until the test holes showed that the proper level could be resumed. This bypassing allowed progress to be maintained. After the heading and bench had passed out of shooting distance it was decided to carry the cast iron tunnel lining beyond the thin point of the roof, in order to insure the safety of the heading.

As the first step in preparation, the concrete cradle and the bottom segments of iron lining were placed in proper position, up to the bottom of the section of roof that required trimming; this work involved no particular difficulty. The flanges of the lining were then well protected with timber, to avoid breakage when it was hit by falling pieces of rock.

At first the plug-and-feather method was considered for trimming the depressed section of roof to the neat line. This method was rejected as too slow, however, and it was decided to try very careful blasting. The results showed the blasting method to be entirely safe and successful. Short trim holes were drilled, loaded and shot, to take out the rock to within a foot of the desired excavation line, for a length of tunnel just sufficient to clear the ring of lining next to be erected. Additional trim holes were then drilled just on the neat line. These holes were spaced about 6 in. apart, and were loaded with about one-eighth stick of dynamite, sometimes every hole but usually only every other hole. Shooting these holes, one by one, took out the arch excavation very close to the neat line, and only rarely required a little hand-trimming in order to allow the iron lining to be placed. The blasting being very light, and the rock weakened by the closely spaced holes, no damage was done to the remaining cover.

As soon as space was cleared for the erection of one plate of lining, the plate was erected and all spaces back of it were filled by driving in rock packing. Operations were then transferred to the opposite side of the tunnel, and clearance was made for another plate. The work thus continued one plate at a time until the entire ring had been completed, and then shifted ahead to the next ring. Booth & Flinn, Ltd., are contractors for this tunnel. M. L. Quinn is their general superintendent, and Sam Allen is shaft superintendent. M. H. Freeman supervises the work for the Public Service Commission.

NEWS OF THE WEEK

New York, May 29, 1919

Sees No Price Reduction in Building Material

Report of Illinois Joint Legislative Commission Recommends State Operation of Plants

Acting under a joint resolution of the legislature of Illinois, a legislative committee has just completed an investigation into the cost of building materials. The commission held a number of public hearings, but confined its attention to the price conditions in brick, cement and lumber. It reported that the costs of brick do not seem to be unduly high, and that there is no evidence of illegal combinations to regulate the price of common building brick. The committee's report on lumber is quite ambiguous. The intimation is that it does not consider the price too high, but no definite statement is made.

In its study of cement it seems to feel that the prices are too high. The committee states, for instance, that a Government expert asserts that the manufacturing cost of portland cement in a 3000-barrel mill should be \$1.25 a barrel, as against an actual cost figure submitted by a cement company of \$1.67 per barrel. It says that it could find no positive evidence of combination of cement manufacturers to establish prices, but that the "circumstances indicate that cement prices are fixed by agreement." The committee also states that the La Salle Portland Cement Co. had net earnings from operations of over 77⅓% on its capital stock, but gives no figures as to the relation of the capital stock to the net investment.

The committee recommends that the interests of the state are so great that it believes the state should engage in the manufacture of cement for public works, as this would have a tendency not only to create competition but would serve to keep the public constantly advised as to the cost of production of the product. As a final conclusion, the committee thinks that prices are at a new level, and quotes approvingly the widespread statement of Prof. Irving Fisher. As a result of the investigation, it is recommended that the state, as trustee for the people, should protect the public from extortionate charges for roadbuilding material, and should be authorized to manufacture products entering into the public improvements of the state. The committee therefore recommends the passage of an act enabling the state to acquire land, mines, quarries, mineral deposits, etc., necessary for raw material, and to lease them, to sell and dispose of products, to enter into contracts with producers for the supply to the state of the raw materials, to extend loans to the manufacturers of such materials, and to permit competition in patented roadbuilding products.

Employment Bureaus

Engineering Societies' Employment Bureau, 29 W. 39th St., New York City.

American Association of Engineers, 29 S. La Salle St., Chicago. Service to members only, but Army or Navy Engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

Engineers' Service Bureau, 57 Post St., San Francisco. Only applications by mail or wire will be considered.

Professional and Special Section, United States Employment Service, 469 Fifth Ave., New York City.

Reëmployment Committee of New York City for Soldiers, Sailors and Marines, 233 Broadway, New York City.

Transit Construction Commissionership Declined by Engineers

With the appointment of John H. Delaney as Rapid Transit Construction Commissioner for New York City, Governor Smith of New York State announces that the position had been declined by Col. William Barclay Parsons, consulting engineer, and by J. Waldo Smith, chief engineer of the Board of Water Supply. Mr. Delaney has until now been the city's Commissioner of Plant and Structures, having charge of bridges and ferries.

Government To Build River Boats

Contracts for boats to be used in the freight traffic on the Warrior River under Federal direction have been let by the United States Railroad Administration, Inland Waterways Division. The St. Louis Boat & Engineering Co., of St. Louis, Mo., is to build four steel, self-propelled tunnel-type boats, for \$244,400 each; the Howard Shipyard & Dock Co., of Jeffersonville, Ind., has the contract for three steel towboats of the twin-screw tunnel type for \$137,000 each, and the Murnan Shipbuilding Corporation, of Mobile, Ala., will build the 20 wooden barges for \$5985 each. Delivery of the steel boats is to be commenced next August.

Federal Highway Commission Opposed by Houston

Secretary of Agriculture Defends Present System—Explains Objection to New Plan

In response to a communication from a city chamber of commerce requesting the views of Secretary of Agriculture Houston regarding the creation of a Federal highway commission and the wisdom of taking the Federal supervision of roads from the Department of Agriculture, Mr. Houston has made a detailed reply. He opposes the commission idea which has been indorsed by chambers of commerce and other organizations throughout the country, and defends the present system. The arguments which are advanced by Secretary Houston are as follows:

Before the advisability of changing the present methods of administering the national highway funds are considered, there are certain facts that it is well to have in mind. First, the importance of roads and the traffic conditions vary throughout the country; second, the state highway departments, being in immediate touch with the situations in their respective localities, are best able to classify and judge which roads will serve the greatest economic needs, and, thirdly, the Federal Government is now aiding the states in considering their technical problems in the selection and improvement of the most important roads, and, when the state department has properly selected a state highway, it generally meets a state highway in an adjoining state and the two become an interstate highway of nation-wide utility.

Furthermore, there is already in existence an excellent organization, the Bureau of Public Roads, which works in a coöperative manner through the 48 state highway departments, under the provisions of the Bankhead Federal-aid road act.

Ample funds have been provided by Congress, the law has been amended to made it work more smoothly, and provision has been made by increasing the Federal allowance per mile, so that roads of substantial character can be built. Altogether, there seems no obstacle in the way, now that the war is over, of the building of those roads which will serve the greatest economic needs.

With the above conditions in mind, the secretary finds it difficult to see what need there is for additional machinery, such as would be required by a Federal highway commission, or, as suggested in a bill introduced in the

last Congress [the Townsend bill, described in *Engineering News-Record* of Feb. 7, 1919, p. 446], which would commit or limit the Federal Government to the construction of two Federally owned and maintained trunk lines in each state.

After calling attention to the fact that there is now in the Federal treasury about $300,000,000 available for roadbuilding, Secretary Houston suggested that it is unlikely that Congress will appropriate additional funds for this purpose, under present financial conditions. He also pointed out the difficulty in diverting the money pledged, from the present appropriations, from the projects for which it has been laid aside, as would be necessary to put the commission plan into effect without further appropriations.

Another problem would be the necessity of changing all the state highway laws, some of which were passed with difficult to meet the new plan. It is doubtful that the states would be willing to change from the present plan of developing the roads serving the greatest economic need to a plan for building two main trunk lines in each state.

Conference on Federal Road Laws Held in Washington

Federal highway legislation was discussed at a conference in Washington on May 20 called by Senator Townsend, author of the Townsend highway bill, for officials of various states and members of the Highway Industries Association. The meeting was attended by representatives from all parts of the country and it is reported that sentiment was very strong for a comprehensive national highway policy along the lines suggested in the Townsend bill. [See *Engineering News-Record* of Feb. 27, 1919, p. 446.]

Among those present were A. R. Hirst, state highway engineer of Wisconsin and president of the American Association of State Highway Officials; G. P. Coleman, state highway commissioner of Virginia and chairman of the executive committee of the organization; Paul D. Sargent, chief engineer of the Maine State Highway Commission; Col. W. D. Uhler, chief engineer of the Pennsylvania State Highway Department; M. L. Cunningham, state highway engineer of Oklahoma; W. S. Keller, state highway engineer of Alabama; Ira R. Browning, state road engineer of Utah; S. M. Williams, president, and H. G. Shirley, secretary, of the Highways Industries Association.

State Buys Two Toll Bridges

State purchase of the Greenbush bridge at Albany and the Congress St. bridge at Troy is provided for by two bills of the legislature recently signed by Governor Smith of New York. Sums amounting to $1,700,000 are made available for the purpose. Tolls collection on the bridges will be abolished.

Sixth Canadian Good Roads Congress and Exhibit

Good Attendance Reported—Resolutions Favoring Federal Aid and Lower Freight Rates Passed

The Sixth Canadian Good Roads Congress and Exhibition, held at the Parliament Buildings, Quebec City, May 20-22, is reported to have been the most successful in the annals of the Canadian Good Roads Association. It started with a motor ride over 180 miles of improved road from Montreal to Quebec. More than 200 delegates were present, and the meetings were well attended.

Keen interest was shown in both the practical and theoretical addresses and papers. The program included addresses on many types of pavement, their construction and maintenance, and on road machinery. The only criticism made of the program was that it was rather overbalanced, the length of the papers curtailing too much the time for discussion. The most interesting exhibit was that made by the Ontario Highway Department, showing models of roads from Roman times down to the present.

The general tenor of the congress is indicated by the resolutions passed at the business meeting: The first petitions the Government, the Board of Railway Commissioners and the railways of Canada for a decrease of 10c. per ton on roadbuilding materials immediately, with an investigation to determine the possibility of a further reduction to a pre-war basis.

The resolution further points out that these rates in Canada have always been higher than in the United States.

Another resolution, dealing with Federal aid, was next passed, as follows:

"Whereas, the Canadian Good Roads Association has heard with the greatest satisfaction that the Dominion Government is contemplating the introduction of legislation with a view of granting financial aid to the provinces toward road improvements;

"And whereas, this association considers that such action would be a highly deserved appreciation of the efforts already put forward by the provinces in this connection and a much needed encouragement to their desire to endow the country with a first-class system of good roads;

"Therefore, be it resolved, that the Canadian Good Roads Association heartily endorses the principle, and strongly urges that it be carried through with the least delay possible."

A general resolution was passed urging the Dominion Government to proceed with any projected bridges affecting international or interprovincial traffic.

The following officers were elected: Honorary president, W. A. Campbell, Dominion Commissioner of Roads; president, S. L. Squire, honorary president of the Ontario Good Roads Association, Toronto, Ont.; first vice president, A. F. MacCallum, commissioner of works, Ottawa, Ont.; second vice president, Dr. E. M. Desaulniers, M.L.A., deputy speaker of the provincial legislature, St. Lambert, P. Q.; secretary-treasurer, George A. McNamee, of Montreal.

New York Governor Signs Bills Affecting Road Contracts

Two bills affecting road contractors have been signed by Governor Smith of New York. One deals with the cancellation of highway contracts made before the war, while the other pertains to the amounts of certified checks to be deposited with bids, and provides conditions whereby bonds for the completion of contracts may be omitted.

The first bill authorizes the termination of highway contracts entered into prior to Apr. 6, 1917, confers jurisdiction upon the Court of Claims to hear claims, determine the extra cost of work due to war conditions, and make awards for increased cost incurred.

The second law provides that all bids on highway contracts shall be accompanied by a draft or certified check for 3% of the amount of the gross bid. This check will be returned when the contract is executed and bonds are provided. The commissioner may, on request of the contractor, dispense with the giving of his bond, in which case 20% of the contract price will be retained until the work is completed.

Septic Tank Patent Claims May Be Settled for Nominal Sum

Settlement of any and all claims of the Cameron Septic Tank Co., Chicago, for alleged infringements of the patents held by the company is provided for in a contract made between the company and the National Septic Process Protective League, Frank G. Pierce, secretary, Marshalltown, Iowa. The company agrees, for the sum of $5000, paid by Sept. 1, 1919, to release from all claims all who may be members of the league on the date named. The agreement also provides for dismissal of the suit brought by the company against Shelbyville, Ky., without cost to either party. The league, through its executive committee, has adopted a schedule of payments to be made by present members of the league or any who may join between now and Sept. 1, 1919, in order to obtain releases under the contract.

Detailed information may be obtained by addressing Mr. Pierce. The attorney for the league has advised that, although he is confident of winning the Shelbyville suit through a decision, and that the American patent expired with the British patent on Nov. 8, 1909, yet that since the cost of the settlement will be so much less than the cost of the litigation, it is advisable to accept the terms of the agreement. The league needs about $10,000 to meet the $5000 payment and all expenses. Any user of a septic tank is eligible to membership in the league and to release from royalty claims.

Third American Concrete Ship Launched

On May 22 the third American concrete ship, and the second to be built by the United States Government, was launched at the yard of the Fougner Concrete Shipbuilding Co., on Flushing Bay, Long Island. The ship, which was christened the "Polias," was described in *Engineering News-Record* of Dec. 12, 1918, p. 1058. It is a 3500-ton vessel, 281 ft. 9 in. long, of 46 ft. beam, and 26½ ft. molded depth. It was designed by the Fougner company and the construction was superintended by the concrete ship section of the Emergency Fleet Corporation. The vessel was stern-launched from the concrete ways and slid off into the water easily and successfully. Four days after launching it was reported to be bone-dry inside, there not being any evidence whatever of leaks or porous percolation. It has been ready for launching for some months, but it has not been possible to put it into the water on account of lack of depth of the offshore basin.

"POLIAS," 3500-TON CONCRETE SHIP, JUST AFTER BEING LAUNCHED

Choose Site for Pittsburgh South Hills Tunnel

A decision reached May 23 by the Allegheny County commissioners, jointly with the county planning committee, fixes the location of the South Hills tunnel, Pittsburgh, soon to be built. A high-level route has been selected, in contrast with the low-level locations of some earlier projects utilizing the Smithfield St. bridge as an approach. The new project provides for a tunnel extending from the Bell House on West Liberty Ave. to the Knox School on Brownsville Ave., and for a bridge over the Monongahela River to Sixth and Forbes Sts. The name "Liberty Tunnel" has been adopted for the entire improvement.

E. K. Morse, consulting engineer to the county, and W. M. Donley, engineer for the planning commission, directed the studies which resulted in the decision that this location will give best service to both the city and the South Hills district. On the question of ventilation, Maj. Gen. George W. Goethals, who was called in consultation, advised that no difficulty would be encountered in keeping the tunnel atmosphere in good condition.

The tunnel will be 5500 ft. long, and will have a single opening 44 ft. wide. Its grade will be 2%. It will serve pedestrian as well as street-car and roadway traffic. A branch tunnel 1000 ft. long to reach Hagerman Ave. is also being considered.

Colorado Engineers Form Engineering Council

At a meeting in Denver, May 16, representatives of eight organizations of the state met and formally launched the Colorado Engineering Council in order, according to its constitution, "to coördinate the work of various technical, scientific, and engineering organizations, promote the welfare and professional standing of their members and foster a more general recognition of the engineer in civil matters." Among the associations represented were the Colorado Scientific Society, the Teknik, the Colorado Society of Engineers and the local associations of the four national engineering societies. The following officers were elected: Arthur Ridgway, president; E. G. Carpenter, vice-president, and Robert J. Grant, secretary and treasurer. Meetings of the council are to be held at least once a month.

Committee to Report on Site of Newark Bay Bridge

A joint committee of the county engineers of Essex and Hudson Counties and the bridge engineer of the New Jersey State Highway Commission has begun the study of the best site and design for a bridge crossing Newark Bay to connect Jersey City and Newark. The bridge would be about two miles long. An appropriation of $15,000 provided by the counties and the State Highway Commission is available for the study. F. A. Reimer of Essex, C. J. Wasser of Hudson, C. A. Mead of the State Highway Commission, and H. W. Hodge, consulting engineer, constitute the committee. Surveys are to be started at once, and meetings will be arranged to determine the wishes and needs of the public in respect to the location of the bridge.

John Fritz Medal Conferred on General Goethals

The formal ceremony of conferring the John Fritz Medal on Maj. Gen. George W. Goethals for his achievements in building the Panama Canal was observed in the auditorium of the Engineering Societies' Building, New York City, on the evening of May 22. Charles F. Rand presided, and addresses were made by William L. Saunders and the Hon. Henry L. Stimson. The latter was Secretary of War during the period when construction work on the canal was most active, and he described his observation at that time of the methods by which General Goethals maintained the *esprit de corps* and the discipline among the army of workers on the canal.

The formal presentation of the medal was made by Ambrose Swasey. In accepting the medal, General Goethals emphasized the credit due many others whose work contributed to the success of the enterprise, mentioning especially President Roosevelt as the one above all others who made the canal possible. Mr. Roosevelt's keen judgment in rejecting the majority report of the International Commission, which he had himself appointed, and adopting instead the minority report which favored the lock canal, saved the enterprise from disaster at a crucial time, he said.

Major General Goethals is the fifteenth engineer to receive the John Fritz Medal, and the third to receive it on account of work in the civil engineering field. The two other civil engineers who have been thus honored are J. Waldo Smith and the late Alfred Noble.

Cedar Lake Sealing Operations To Be Resumed

Sealing the Cedar Lake reservoir of the Seattle municipal water-works, officials of the water department announce, will be resumed as soon as the water goes down enough to leave a dry basin. The work done in 1918 had hardly progressed beyond the preliminary stages when the autumn rains made it necessary to close down work for the winter. The city retained J. D. Blackwell, consulting engineer, of Seattle, to make a further study of the plans for sealing the basin by sluicing methods, and his work has been carried on actively during the rainy season of the year.

Civil Service Examinations

New York.—Heating and ventilating engineer, office of state architect, $1500 to $2500 per year, June 28, apply to State Civil Service Commission at Albany for application forms before June 16.

United States

For United States civil service examinations, listed on the following page, apply to United States Civil Service Commission, Washington, D. C., or to any local office of the commission, for form 1312.

Chief of road survey party, $1800 to $2100 per year, transitman for road surveys, $1200 to $1800 per year, highway draftsman, $1200 to $1800 per year, Bureau of Public Roads and Rural Engineering, May 29. File applications before May 29.

Senior engineer and senior architect, Interstate Commerce Commission, $1800-$2700 per year, June 10. File application before June 10

Assistant designing engineer, Naval Ordnance Plant, South Charleston, W. Va., $9.20 per diem. July 8. File applications before July 8.

Valuation engineer, $3600-$4800 per year, and assistant valuation engineer, $2500-$3600 per year; technical staff, income-tax unit, Bureau of Internal Revenue, Treasury Department. No date specified.

Master computer, $2400 to $1800 per year, computer (Grade I) $1800 to $1400 and computer (Grade II) $1400 to $900, Ordnance Department. Applications will be received until further notice.

Engineering Societies

Calendar

Annual Meetings

AMERICAN WATER-WORKS ASSOCIATION; 47 State St., Troy, N. Y.; June 9-13, Buffalo, N. Y.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, 29 W. 39th St., New York; June 16-19, Detroit.

AMERICAN SOCIETY OF CIVIL ENGINEERS; 29 W. 39th St., New York; June 17-20, St. Paul-Minneapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS; University of Pennsylvania, Philadelphia; June 24-27, Atlantic City, N. J.

AMERICAN CONCRETE INSTITUTE; 6 Beacon St., Boston; June 27-28, Atlantic City, N. J.

The American Society of Marine Draftsmen will hold its eighth annual meeting at the Hotel Brunswick, Boston, June 20-21. The officers of the society are: President, Alfred H. Haag, chief naval architect, United States Shipping Board; vice-president, W. A. Leavitt, Jr., New York Shipbuilding Corporation; secretary, B. G. Barnes, Lake Torpedo Boat Co.; treasurer, J. Binford Sadler, industrial department, United States Navy Yard, Norfolk.

The Montreal Branch of the Engineering Institute of Canada will tender a banquet to Brig. Gen. Charles Hamilton Mitchell, C.B., C.M.G., D.S.O., in the first part of June. General Mitchell is returning to Canada to reënter civil life after nearly five years in overseas service He has been decorated by the Governments of France, Belgium and Italy, as well as by Great Britain.

The Society of Terminal Engineers held its annual meeting in New York City May 20. Francis Lee Stuart, chairman of the engineering committee, United States Railroad Administration, previously chief engineer of the Erie and Baltimore & Ohio R.Rs., was elected president. Other officers elected for the coming year are: Vice-presidents, John Meigs, E. H. Lee, Calvin Tomkins, Charles Whiting Baker and Maurice W. Williams; treasurer, W. Joshua Barney; secretary, J. H. Leonard.

The Engineers' Club of Philadelphia elected the following officers at the annual meeting May 20: President, Joseph A. Steinmetz; vice-president, Paul Spencer; secretary and treasurer, Lewis H. Kenney. The club's last weekly luncheon of the season will take place June 3 and will be addressed by Dr. Samuel C. Sadler, on "American Potash and Its Sources."

The St. Louis Chapter of the American Association of Engineers has been elected a member of the Associated Engineering Societies of St. Louis, which body has unanimously approved the schedule of wages for city employees adopted by the St. Louis Chapter and its municipal section.

The New York Chapter of the American Association of Engineers has elected the following officers: President, Alexander Potter; vice-presidents, J. C. Patterson and Maurice Griest; treasurer, Hugh C. Jackson, and secretary, E. B. Miller, 294 Henry St., Brooklyn, N. Y.

The Chattanooga Chapter of the American Association of Engineers held a regular meeting May 21 at which the following temporary officers were elected: Chairman, J. L. Earles; vice chairman, R. E. Elgen: secretary-treasurer, Ray Dunlap.

The Pacific Coast Good Roads Association will hold its annual meeting in San Francisco June 25-26. The association is working in coöperation with the Pacific Coast Defense League, Inc., to provide a system of military highways on the Pacific Coast.

The Oregon Society of Engineers was addressed May 23 by Capt. J. W. Morris, Engineers, U. S. A., former city engineer of Portland, who spoke on his experiences as an Army engineer with combatant troops.

The Cincinnati Chapter of the American Association of Engineers was formally installed May 24 and was addressed by W. H. Finley, president of the national organization.

The Albany Society of Civil Engineers held a meeting May 27 at which S. T. Dodd spoke on the "Electrification of the Chicago, Milwaukee & St. Paul Ry.," the paper being illustrated by motion pictures.

The Rochester, N. Y., Engineering Society made a trip of inspection May 24 to the mines and plant of the Empire Gypsum Co., at Garbutt, N. Y.

Personal Notes

PROF. FRANK P. MCKIBBEN, head of the department of civil engineering at Lehigh University since 1907, has accepted an appointment, effective on Sept. 1, as professor of civil engineering at Union College, Schenectady, N. Y. Professor McKibben was graduated in 1894 from the Massachusetts Institute of Technology, and until 1907 served successively as instructor, assistant professor and associate professor in the department of civil engineering. During this time he was engaged also in work as assistant engineer for the Boston Elevated Railway Co., and the Massachusetts Railroad Commission. In 1907 he was appointed professor of civil engineering at Lehigh University, succeeding Dr. Mansfield Merriman. In 1918 he inaugurated a course in shipbuilding.

MAJ. EUGENE W. STERN, Engineers, U. S. A., who recently returned to this country and received his discharge from the service, has opened an office for the practice of engineering at 56 W. 45th St., New York City. Mr. Stern resigned as chief engineer of highways, Borough of Manhattan, New York City, to enter the Army.

MAJ. CLARENCE GOLDSMITH, Construction Division, U. S. A., who recently received his discharge from the service, has resumed his work as engineer for the Committee on Fire Prevention and Engineering Standards, National Board of Fire Underwriters, with office at 76 William St., New York City.

CAPT. PAUL HANSEN, Sanitary Corps, U. S. A., has returned to this country and has received his discharge from the service. He has resumed his position as chief sanitary engineer, Illinois State Department of Public Health, with headquarters at Springfield.

LIEUT. C. C. SADLER, U. S. A., who was assistant to the utilities officer at Camp Jackson, Michigan, has received his discharge from the service and has resumed his position as field engineer, coke plant, American Steel & Wire Co., Cleveland.

J. M. DUGAN and R. E. CHRISMAN, formerly with the Sound Construction & Engineering Co., Seattle, recently returned to Seattle from California and have become associated in partnership to engage in engineering and construction work, with offices at 312 Boston Block, Seattle.

R. J. WINDROW, of Waco, Texas, has been elected state highway engineer of Texas by the State Highway Commission, succeeding GEORGE A. BUREN, who has retired to private practice. Mr. Windrow is a graduate in civil engineering from the Agricultural College of

Texas, and has had extensive experience in roadbuilding in McLennan County, Texas. He recently resigned as city engineer of Waco to engage in contracting.

HENRY OAKES, Engineers, U. S. A., who recently received his discharge from the service, has been appointed city engineer of Muskegon Heights, Mich., in place of VICTOR BURTON of Lansing, to whom the office was offered but who was unable to accept the appointment, made several weeks ago.

CAPT. HENRY E. ROBERTSON, 344th Machine Gun Battalion, U. S. A., has received his discharge from the service and has resumed his work with the El Paso Bridge & Iron Co., El Paso, Texas.

MAJ. ROBERT I. RANDOLPH, 535th Engineers, U. S. A., has received his discharge from the service and has resumed his work as a member of the firm of Isham Randolph & Co., consulting engineers, Chicago.

L. A. WEATHERWAX, Hendrickson Construction Co., Seattle, and former secretary of the Seattle Master Builders' Association, has become associated with Stone & Webster on hydro-electric work at Fresno, Calif.

COL. H. M. WAITE, Engineers, U. S. A., has received his discharge from the service and has become associated with the Lord Construction Co., New York City, as vice-president and chief engineer.

C. A. DUNN, division engineer, State Highway Department of Oregon, with headquarters in Salem, has resigned to become general superintendent for Oscar Huber, contractor, Portland.

H. C. HEDDINGER, who for some time has been associated with the Aberthaw Construction Co., Boston, has been placed in charge of the new permanent office of that company in Buffalo, at 918 Ellicott Square.

DALTON MOOMAW, formerly road engineer of Cuyahoga County, Ohio, with headquarters in Cleveland, has been appointed county road engineer of St. Joseph County, Indiana, with office in South Bend.

HARRY BOLLINGER has been appointed city engineer of Columbia City, Ind., succeeding CLAUDE ANSPAUGH, who has resigned to devote his entire time to the duties of county surveyor.

LIEUT. CLARENCE A. LIVINGSTON, Signal Corps, U. S. A., has received his discharge from the service and has become associated with D. H. Burnham & Co., architects, Chicago.

GEORGE O. WITH, assistant manager, Consolidated Expanded Metal Co., Chicago, has been appointed city engineer of Joliet, Ill. He was previously assistant city engineer of Chicago Heights, Ill., for two years. During the war he served as chief carpenter's mate, Great Lakes Naval Training Station, in charge of sewer construction and water-supply. Previous to this service he was in the field service department of *Engineering News-Record*.

CAPT. E. P. RANKIN, JR., 110th Engineers, U. S. A., has received his discharge from the service and has returned to his work with the El Paso Bridge & Iron Co., El Paso, Tex.

PERRY FILKIN, division engineer, New York State Highway Department, has been transferred from Rochester to Hornell, succeeding S. E. FITCH, transferred to Utica.

ARTHUR A. SMALLEY, assistant city engineer of Pleasant Lake, Ind., has resigned to become assistant city engineer of Hamilton, Ohio.

ERNEST BRUCE, civil engineer, Charleston, W. Va., has been appointed chief of the engineering department of that city, succeeding HARRY WILEY, resigned.

E. R. KENNER has been placed in charge of the new permanent office of the Wellman-Seaver-Morgan Co. at Atlanta, which is located at 318 Hurt Building.

O. E. ECKERT, formerly with the engineering division, Michigan State Board of Health, has been appointed city engineer of Lansing, Mich.

WILLIAM S. MURRAY, consulting engineer, New Haven, Conn., has removed to 165 Broadway, New York City.

WALTER BOWMAN has been appointed city engineer of Harvard, Ill.

STEPHEN PALMER, of Clarksburg, W. Va., has been appointed county road engineer of Wetzel County, West Virginia.

BLAINE H. MILLER has resigned as building commissioner of Indianapolis, Ind., to devote his entire time to private business.

HARRY B. COOK, of Atlantic City, has been appointed a member of the State Board of Commerce and Navigation of New Jersey to fill the vacancy created by the resignation of Allen K. White.

OBITUARY

ALLEN E. NICHOLS, consulting engineer, Chicago, died in that city, May 8, at the age of 31. He was graduated from Purdue University in 1910, and for two years following was engaged in railroad work with the Baltimore & Ohio R.R. and the Chicago & Western Indiana R.R. He then became associated with Alvord & Burdick, consulting engineers, Chicago, engaged in sanitary engineering work. He served for two years as assistant engineer in charge of contracts and design of the municipal reduction plant and incinerator under Col. Henry A. Allen, for the Bureau of Waste Disposal. During the war he was employed by the du Pont Engineering Co. as assistant engineer of construction on the 70,000,000-gal. filtration plant for a powder plant at Old Hickory, Tenn. He had recently opened a consulting office in Chicago, in connection with his father, specializing in garbage and waste disposal.

CAPT. HENRY B. SAUERMAN, Engineers, U. S. A., who was one of the organizers of the first company of Army engineers in the State of Illinois, died in Chicago, May 20, at the age of 40. He was a member of the firm of Sauerman Bros., engineers and manufacturers of construction equipment, Chicago. He entered business in the employ of Fairbanks-Morse & Co., where he remained for 11 years, first as chief draftsman and later as contracting engineer. In 1911 Mr. Sauerman joined his brother, John A. Sauerman, in organizing the firm of Sauerman Bros., succeeding the H. N. Elmer Co. When the original Co. A, Engineers, Illinois National Guard, was formed in 1911, Captain Sauerman enlisted for three years as a private, but was elected captain a year later. In 1918 he received the Octave Chanute medal from the Western Society of Engineers for his paper "Fortification," which was prepared for a meeting of the society in 1916 and was later published as a handbook for Army engineers. Later his booklet, "Highways and Railways for the Defense of Our Nation," attracted considerable attention.

WILLIAM TRUTCH PRESTON, principal assistant engineer, United States Engineer District, Seattle, died in that city May 14. He was born in 1859 and went to the Canadian Northwest as a civil engineer in 1880. He had charge of construction work on the Canadian Pacific Ry., including that in Frazier River cañon. Later, for two years, Mr. Preston was engaged in construction work for the Seattle, Lake Shore & Eastern R.R. Since 1896 he had been continuously in the service of the United States Government. He was connected with fortification work in the Boston district for five years, and with river and harbor fortification work in the Seattle district during the remainder of his service. The major portion of the fortification works of the coast defenses of Puget Sound was constructed under Mr. Preston's supervision. He was also connected with the construction of the Lake Washington ship canal. During 1918 he was in charge of the Seattle district as district engineer.

LOUIS ARTHUR KINNEAR, of the engineering staff of the Ontario Hydro-electric Commission, died at Nipigon, Ont., May 12. He was graduated from Queen's University, Kingston, in 1912, and acted as engineer for several municipalities.

New Semi-Trailer Has Collapsible Auxiliary Wheels

A new tractor and semi-trailer designed to facilitate coupling and uncoupling, and to allow for turning in the shortest possible radius, is shown in the accompanying illustration. This trailer, having four wheels when uncoupled, may be shifted around for loading without the use of the tractor. The outfit shown is the regular four-ton unit, being manufactured by the Fulton Motor-Truck Co., of Farmingdale, N. Y.

TRACTOR AND SEMI-TRAILER MAKING A SHORT TURN

The main features of this transportation unit are the method of coupling and the collapsible wheels on the front of the trailer which rest on the ground while it is being loaded, and allow for shifting.

To facilitate coupling, the tractor has two flared runways at the rear, one on each side, which pass under two small wheels on the bottom of the trailer body. As the tractor backs up to the trailer, these small wheels run up the inclined runways, lifting the front of the trailer from the ground. As the wheels pass up the runways, they are controlled by guides on each side, which bring the coupling device into position. The coupling is completed automatically. By means of a hand lever, the front supporting wheels of the trailer may now be lifted and clamped free of the ground, as shown in the view.

The two small forward wheels which guide the coupling device up the runways rest and roll upon a circular wheel similar to a turntable, thus steadying the trailer. When it is desired to uncouple the trailer, the operation is controlled entirely from the driver's seat. By pulling a lever he releases the front supporting wheels of the trailer, which are thrown into a vertical position. At the same time the brakes on the rear wheels of the trailer are set, and the tractor can be freed and attached to another trailer.

National Association of Manufacturers Elects Officers

At a meeting of the board of directors of the National Association of Manufacturers, held in the Waldorf-Astoria Hotel, New York City, following the 24th annual convention of the association, the following officers were elected: President, Stephen C. Mason; treasurer, Henry Abbott; general manager and assistant treasurer, J. Philip Bird; secretary, George S. Boudinot.

Very Little War Motor Equipment to Be Sold

A comparatively small amount of used passenger and commercial cars, not adapted to Governmental use, will be sold at public auctions to be held at various military posts and camps beginning June 1, according to C. W. Hare, director of sales. The major portion of all present surplus motor equipment is now being transferred to Governmental departments. Over 10,000 motor trucks, passenger cars, ambulances and motorcycles have already been transferred, deliveries having been made to the Postoffice Department, the Public Health Service and the Department of Agriculture, the latter having received about 5000 trucks to date. As fast as the several states place in operation the consignments made through the Department of Agriculture, the director of sales will transfer additional trucks and roadbuilding machinery. The needs of the departments mentioned are expected to absorb practically the entire surplus of motor vehicles acquired for military purposes.

BUSINESS NOTES

THE ALLIED MACHINERY CO. OF AMERICA announces that it has increased its capital stock to $5,000,000. This was made necessary by the decision of the American International Corporation to group all of its machinery export selling subsidiaries under one head, completely absorbing the Allied Construction Machinery Corporation. The Allied Machinery Co. de France, the Allied Machinery Co. d'Italia and the Horne Co., Ltd., of Japan, while retaining their corporate entities, will also be directly connected with the Allied Machinery Co. of America, rather than the American International Corporation, as before. The Allied Machinery Co. of America is at present operating in 14 countries. J. W. Hook will continue as president. F. A. Monroe, in charge of administrative affairs, S. T. Henry, in charge of sales and advertising, and T. G. Nee, devoting his attention to the affairs of the Horne Co., Ltd., have been elected vice-presidents. R. P. Redier is general sales manager of the company, with headquarters in Paris.

THE STANDARD ELECTRIC AND ELEVATOR CO., of Baltimore, has opened a New York office at 280 Broadway, in charge of C. A. Yarrington, formerly sales manager of the company. M. H. Jones, with the Westinghouse Electric Mfg. Co. for 15 years, has resigned to succeed Mr. Yarrington as sales manager of the Standard company.

THE MASSEY CONCRETE PRODUCTS CORPORATION announces the opening on June 1, of a Pittsburgh office at 1405 Oliver Bldg., with A. F. Humphrey as resident manager. It also announces the appointment of J. A. Higgs, Jr., as resident manager of the Southeastern district, with headquarters in the Candler Annex, Atlanta, Ga.

THE CENTRAL FOUNDRY CO., New York City, announces that George A. Harder has been elected president and director of the corporation and its subsidiaries. Mr. Harder is also president of the Essex Foundry Co., Newark, N. J.

TRADE PUBLICATIONS

The following companies have issued trade publications:

THE JAEGER MACHINE CO, Columbus, Ohio; two catalogs, 7¾ x 10¾ in., 32 pages, and 6¾ x 10 in., 16 pages, illustrated; describe concrete mixers and the layout for their use.

THE LOCOMOTIVE SUPERHEATER CO., 30 Church St., New York City; Bulletin T-2, 8 x 10½ in., 8 pages, illustrated; describes the use of "Elesco" superheater to secure the advantages of the use of superheated steam in stationary boilers.

THE BUFFALO FORGE CO., Buffalo, N. Y.; section 400 of the catalog, 5 x 7½ in., pp. 403-436, illustrated; pertains to fans, blowers and exhausters.

THE WHITING FOUNDRY CO, Harvey, Ill.; folder, 8½ x 11 in., 4 pages, illustrated; gives names of users and describes Whiting bucket cranes.

WILLIAM H. WOOD, hydraulic engineer, Media, Delaware County, Penn.; catalog, 63 pages, illustrated; embraces all kinds of hydraulic machinery and improved locomotive boilers.

THE T. L. SMITH CO., Milwaukee, Wis.; two pamphlets, 7½ x 10¾ in., 16 pages each, illustrated; concrete mixers for paving work and pumps for construction and industrial work are the respective subjects.

A Consolidation of Engineering News and Engineering Record — McGraw-Hill Company, Inc.—JAMES H. MCGRAW, President

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING AND CONTRACTING

E. J. MEHREN, Editor — CHARLES WHITING BAKER, Consulting Editor

Volume 82 — NEW YORK, THURSDAY, JUNE 5, 1919 — Number 23

Chicago Leads in Centrifugal Pumping

BY FAR the largest aggregation of centrifugal pumping machinery for water-works purposes is that of Chicago, which includes 16 plants having a combined capacity of about 400,000,000 gal. per day, with over 60% of the volume lifted electrically. The record of the growth of the Chicago installation, given on p. 1114, is a chapter in the development of large centrifugal pumping units for water-works plants that is well worth reading.

Water-Works Association Growth

GROWTH has been shown by the American Water-works Association for several years. This applies both to numbers and efficiency, but perhaps more notably to membership and to sectional organization than to the volume and character of work done. In fact, even before we got into the war there appeared to be a decline in accomplishments, at least as regards committee work. Naturally, the war checked committee work still further. It should now be resumed along well considered lines and with vigor. In particular, the committee on cast-iron pipe specifications should complete its work of revision and of unification of the American and New England specifications. There might well be a committee on methods of paying for water-main extensions, directed to gather extensive data on methods in use, to compare the merits and demerits of the several plans and to draw conclusions as to the best plan, or the most desirable plans from which to choose, to meet prevalent types of local conditions. In such a study particular attention should be given to assessments for benefits. These are only two of many kinds of committee work that might be mentioned as possibilities.

Public Service Through Technical Discussion

NOT often does an engineering society give such direct service to the community through technical discussion as did the American Society of Civil Engineers with its recent symposium on the Hudson River highway tunnel, recorded in the May *Proceedings* of the society. By taking up an urgent problem, one of exceptionally formidable engineering aspect, and giving opportunity for the free expression and clarification of opinion on its solution, the society afforded important help to the community in its largest present enterprise. Coming at the time when the technical organization of the Hudson tunnel work is being perfected, the discussion will almost at once produce a tangible gain to the community. It marks out the field within which must develop the final solution of the tunnel-construction problem on which New York and New Jersey have just agreed, and thereby it gives to the public the advantage of surer engineering decision, which will mean more efficient performance. Furthermore, the facts and views brought out in the symposium establish, if one will read between the lines, the urgent need for better intercommunication between New York City and its New Jersey outliers more convincingly than has yet been done. They tend to define the land-traffic problem of this terminal as a unit problem—one of great magnitude—and raise the question whether the trans-Hudson traffic situation is not more serious than even the most ardent advocates of bridge and tunnel projects have yet ventured to claim. The issues here, involving additional crossings of the river and elaborate connections for these crossings, are so weighty that only by focusing the full power of engineering thought upon the subject can a sound program of action be constructed. The society's discussion was the first step toward creating this condition.

Engineers for Hudson Tunnel

ANNOUNCEMENT has been made that six consulting engineers will be appointed to advise on the vehicular tunnel to be built under the Hudson between New York and Jersey City. Time was when it appeared that one plan—that for the 42-ft. single tube—had the clear right of way. Though proposed by an able tunnel builder and approved by an able engineer, obviously a project departing so far from standard practice requires not only close scrutiny in itself but detailed comparison with tried methods of construction. There are no less than four plans proposed, two concerned chiefly with type and two with construction methods—the large tube, a pair of tubes of customary size and two variants of the trench method of construction. Presumably, the engineers will be selected for their familiarity with the types of construction proposed; this, of course, does not apply to the large single tube, for that is unprecedented. The principle of the procedure is correct, that of a broad study of the question. If the appointments agree with the principle the commissioners will have competent data to guide their decision.

Municipal Rain-Gages

"THERE are far too few rainfall stations," said Robert E. Horton a few months ago (*Engineering News-Record* of Mar. 27, 1919, p. 614), in pointing out the inadequacy of our hydrological data. His statement has just had renewed illustration. During the heavy rainfalls of the past month many towns and cities reported short-time storms of unusual intensity. Rainfall rates exceeding any previously known are said to have occurred in some cities; tangible evidence such as the amount of water caught in vessels standing in the open confirms mere impression in this matter. Were local drainage works to be built in those cities, a definite measurement of the new maximum rainfall rate reached would be important, but for lack of a rain-gage no

measurement was obtained. A few cities maintain gages; most do not. May it not fairly be considered a proper municipal engineering function to provide rain gages and to keep exact records?

Flying the Atlantic

IN THE broad annals of engineering last week will mark an epoch. For the first time the Atlantic Ocean was crossed by man in the air. Those of us who have not followed closely the development of flying little appreciate the amount of painstaking engineering study and investigation that has gone into making that flight possible. We speak not of the details of Commander Read's crossing of the ocean, nor of the design of his plane and its accessories. We are thinking of all that has gone before in the way of study and experimentation, of the thousands of planes built only to be scrapped, of the thousands of lives that have been risked and lost in order that we might come to the NC-4 and her triumph. We are thinking, too, of our own Chanute and of Langley, of happy memory. Much as the thoroughness of the preparations, the weather reports and the bridge of ships extending from Newfoundland to the Azores, to Portugal and to England may detract from the possible romance of an Atlantic flight, the accomplishment is a tremendous one. It has furnished, so aëronautical experts tell us, many valuable data on which to base further oversea flying feats, and it will act as a stimulus for others to do their utmost, not merely to duplicate the feat, but to surpass it by a nonstop flight from land to land. From the historical standpoint, the outstanding fact is that the first successful flight from the Western to the Eastern continent—a distance by the Azores of 2150 nautical miles—was accomplished in 26 hours and 47 min. of actual flying time. Therein lies the compelling motive in the development of the method of flying—that it will bring the two continents much closer than they are today. Imaginations stirred by such an event can rove wildly, but he would be dull indeed who did not live in the expectation of mail transmission between Europe and America consummated in the space of a single day. As a regular method of postal conveyance, such a feat may be a few years off, but it has plainly been brought within the realm of probability.

City Planning Progress

TWENTY years ago city planning was a term rarely used in America, and then only by a few men who were almost universally held up to amusement or contempt as idle dreamers. Ten years ago the need for city planning had obtained sufficient recognition on this side of the Atlantic to warrant the holding of a conference on the subject. Similar conferences have been held year after year ever since. These have shown growth in numbers and in concreteness of discussion. At the start few engineers were in attendance. Year by year the number has increased, until, at the conference held May 26-29, 1919, at Niagara Falls, perhaps a fourth of the members were engineers. The proceedings of all the city planning conferences have dealt almost exclusively with severely practical matters, nearly all of which are within the engineering field as commonly understood and practically all of which are included within any broad view of municipal engineering. Of this no better evidence could be offered than the abstracts of conference papers and the report of the meeting given on pp. 1079 and 1133 of this issue. Many of the more progessive municipal engineers of the country are already members of the conference. The number should increase.

The Development Committee

AT MINNEAPOLIS there should be opportunity for crystallization of views with reference to the development committee of the American Society of Civil Engineers. The question should come up at the business session of the convention; it surely will in the corridor talk. In New York in January the preliminary report of the committee was passed without comment. No food for thought had been offered by the committee. The time available had been too short. The situation as far as it concerns measures proposed for discussion has not improved. But there is the difference that six months have gone by, six months that have multiplied questions as to what the development committee was doing and what good would come of it. In those six months, too, has come the demand that the executive power of the committee be changed at intervals. It will be singular indeed if after six months of silence the Minneapolis-St. Paul convention should pass without the taking of bearings on this important question.

Service Rather Than Honor

THE coming meeting of the nominating committee of the American Society of Civil Engineers makes apropos the repetition of a thought expressed at a meeting in New York in March. J. E. Johnson, Jr., since deceased, described many of the men elected to office in our national societies as men who had won reputations and who were afraid of damaging them by starting something new. While the particular turn he gave his thought renders it liable to dispute, it is true, as was expressed in these columns in the issue of Apr. 3, 1919, that in seeking to honor men by electing them to office we have at times sacrificed the interests of the societies. The older men have come to the time of life when they take up new problems with less energy, when the inclination is strong to be content with that which is. Age, however, is not essentially a disqualifier; rather, mental alertness and freshness of view are to be looked to. There are men who are old at 45 and others young at 70. The late Dr. Corthell, notably, belonged to the latter group. In these days, when new conditions are pressing upon us, the standard for selection, we should think, would be ability *and inclination* to serve the society.

Simpler Geometry of Compound Curves

ALTHOUGH the formulas for the treatment of the geometry of compound curves developed by Mr. Llano on page 1070 of last week's issue are not all new, they are apparently simpler theoretically and more convenient practically than any others heretofore developed. Being derived in a systematic way from a few sets of fundamental equations without the necessity of drawing special figures or going through any special investigations for every particular case, they make unnecessary the introduction of auxiliary quantities. They are an improvement over the methods adopted by other writers because they reduce to a minimum both the work itself and the probabilities of error. The apparent simplicity sometimes indicated in textbooks is often misleading, because when application is made it is found that the actual arithmetical work is exceedingly laborious and often involves much unnecessary duplication. While

compound curves are not now so frequently used in steam railroads, the spiral being generally resorted to as more efficient and economical, in minor roads and especially in street railways the compound circular curve is much used. Furthermore, in the original location of steam railroads running through open country, compound curves are usually determined by assuming the two radii and central angles and computing the tangent distances. Certain auxiliary circles given in the article will be found most helpful in the solution of such problems. In street railways, on account of limited space, many of the problems solved in this article are likely to arise. For example, in the construction of the Lexington Ave. cable road in New York City, the assumed directions of the tangents to connect with the Broadway line at 23d St. were found to interfere with the intricate system of water, gas, and electric pipes, making it necessary to change the alignment by swinging a tangent about one of the tangent points. This led to the solution of one of the problems given in the article.

Engineers Decline Executive Post

MUCH comment has been occasioned at New York by the reported refusal of certain New York engineers of the post of transit construction commissioner. They were good engineers, able executives, the comment runs—why, then, did they decline a post concerned exclusively with the execution of engineering work? We are not in a position to answer for the engineers in question, but we do know that the post is not an enviable one. All our readers will remember the hamstringing of the commission by the Board of Estimate and Apportionment when some 300 engineers were dropped last winter. It is a position of apparently large responsibility, with the incumbent's hands effectively tied, if the board wishes to tie them. The case, then, is not typical. It is likely to be a position beset with much grief.

Executive Versus Technical Ability

THE declination by engineers of the post of transit construction commissioner at New York, discussed in the preceding note, brings up the old question of engineer executives. Fortunately, we are class-conscious. We like to see one of our own number succeed, not merely for his own sake, but because of the luster he sheds on the profession. We believe, too, not without reason, that, given two executives of equal executive ability, the one with engineering training, if the position is one in charge of engineering work, will give the better account of himself. He will grasp the problems more quickly; his analytical ability, developed by his scientific training, will enable him more certainly to get at the essentials. But in the enthusiasm for our fellows and our profession we ought not to lose sight of the fact that executive work is distinct from technical work, and that success in it springs from qualities not necessarily developed in an engineering course. In fact, the qualities are but little developed in any college course. They depend more upon inherent qualities and on those developed outside of college—or at least outside the classroom—than upon book-training. The appointing officer, looking for a capable executive, must seek executive qualities first. If for a job much concerned with engineering he finds an executive who is also an engineer, so much the better—but his first responsibility is to find the executive. When we come to the appointment of an engineer as a member of a commission charged with an engineering project the situation is somewhat different. The transit construction commissioner at New York is a sole commissioner. As a rule, the qualifications needed on a board are judicial, rather than executive, and here the engineer will be invaluable, even though he does not possess executive ability. Of one thing though, there must be warning—of the temptation of an engineer-commissioner, or of an engineer-executive, to become the chief engineer as well. Confusion of judicial or purely executive work with technical detail is likely to lead to disaster.

Water-Supply and "Mobexpertocracy"

THE delay in obtaining a pure and adequate water-supply for Sacramento, Calif., has continued so long that, according to an editorial in the Sacramento *Union*, "gray-haired men are numerous in this city who remember the eternal discussion over a municipal water-supply that went on when they were boys. From that day to this not an advance has been made." The course of events shows how a city should not go about securing a water-supply. "Mobexpertocracy" was a word used editorially in *Engineering News-Record* of June 14, 1917, to denote the chief obstacle to progress. In the main the conditions deplored then still obtain.

The unusually comprehensive report covering well, river and mountain sources that was prepared three years ago by Messrs. Hyde, Wilhelm and Miller has not been acted upon. It seems rather to have added fuel to the fire of debate and discussion, despite the fact that there is no question about the capability or the unbiased judgment of the engineers who made the report. Since the first of this year a citizens' committee, unable to reach a conclusion, has called in C. E. Grunsky to add to the engineering reports on the subject. After a careful study Mr. Grunsky recommended the immediate construction of a filtration plant for purifying river water. The committee was wise enough to indorse the recommendation. An election has been called for June 26 to vote on a bond issue of $1,800,000 for carrying out the project recommended—a slight modification of the Hyde plan.

The use of wells as a source of supply, so strongly urged by one faction in the controversy, has not been recommended in either of the two reports mentioned because of the uncertainty of their yield, the litigation that would probably result from lowering the water table, and the question as to whether unsafe surface waters could be excluded. To avoid affecting the water table, wells would have to be near the Sacramento or American River, in which case a purification plant would be needed. A mountain supply, desirable though it may be, is not now feasible, it has been agreed, because of its high cost, but should the time come when it is feasible the proposed river filtration plant would become a standby or safety feature.

Engineering News-Record has no brief for any of the sources, but when experts agree, as they have in this case, and when exhaustive studies indicate some safe and sure means of relief, then it is not only unwise and unprogressive, but it is unlike our American spirit, to heed the lay "experts" who have nothing constructive but only pet theories to offer.

The issue seems to be clear. It will be interesting to see what the voters of Sacramento decide on June 26.

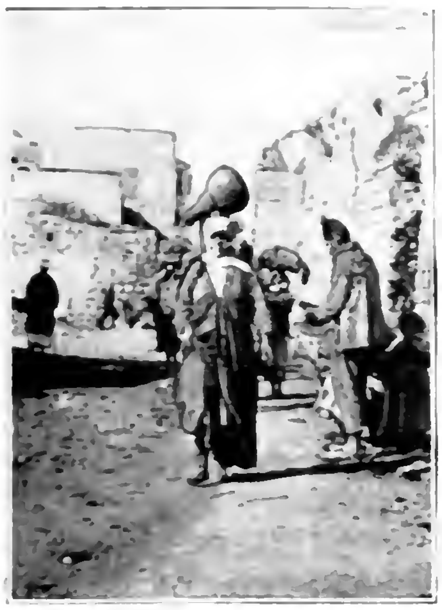
Ancient, War-Time and Present Water-Supply in Jerusalem

How General Allenby's Engineers Brought Water from Nile Across Desert—Ancient and New Permanent Water-Supplies of Jerusalem—Important Part Played by Caterpillar Tractors and Modern Pipe

By H. Y. Carson

Lately Captain and Sanitary Engineer, American Red Cross Commission; now With the Central Foundry Company, New York City

IN CARRYING the work of the American Red Cross into Palestine, following the reclamation of the Holy Land by the British troops, one of the first duties undertaken by the commission was that of surmounting the troubles occasioned by lack of proper housing and sanitation. Many of the troubles were due, primarily, to the difficulty of obtaining pure water.



IN THE VILLAGE OF RAMLEH

Carrying water jars on the head is still common in all Palestine.

The introduction of water into Palestine from the Nile is said to have been predicted thousands of years ago. It is no longer a prophet's dream, as the Nile water was brought to Palestine by General Allenby's able engineers when they fought successfully over the desert more than a year ago. American pipe and American equipment, joined with British ingenuity, accomplished the thing which had been foretold so many years ago. Caterpillar tractors hauled the pipe from Egypt over the sand of lower Palestine. The pipe and tools were the property of the Standard Oil Co., and were stored in Egypt just prior to the war. They were to have been used for piping oil from the recently developed oil fields there.

The water brought into Palestine at the rate of several million gallons per day was pumped from the so-called "sweet-water canal" near Kantara which has its source in the Nile. The British Royal Engineers erected at Kantara rapid sand filters very much like those on the Mississippi and Ohio Rivers. The plant at Kantara had a capacity of 5,000,000 to 10,000,000 gal. of water daily. Pumps sent by rail from Cairo impelled the purified Nile water through a 12-in. pipe across the Suez Canal and about 50 miles beyond the desert. At this point the water not actually used along the line was "picked up" from a newly constructed reservoir and delivered into a 10-in. pipe through which it was carried northward about 40 miles. Originally it was again pumped through an 8-in. pipe line some 50 miles to Gaza, but this force main has since been discontinued.

The pipes were laid directly in the sands of the desert and followed for the most part a parallel with the newly constructed railway. All of the piping, except for expansion joints, was covered with the soil or sand to a depth of 18 in. or more, thus protecting both the pipe and the water from the intense heat of the Palestinian sun. These waters of the Nile served only the lower portion of Palestine, the supply for such cities as Jerusalem, Gaza, Beersheba and Jericho being obtained from local sources, springs, wells, etc., some of which yield an abundance of pure water, others a scanty supply.

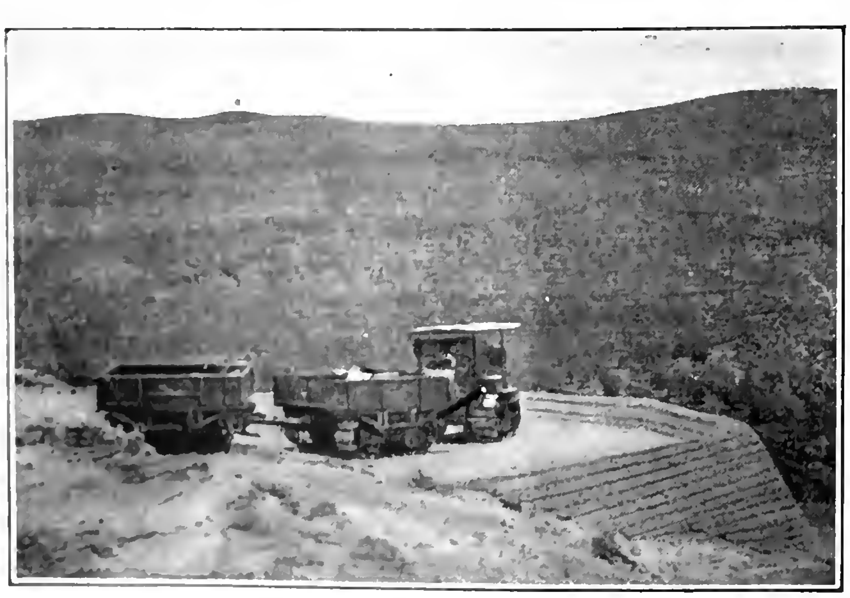
Under the surface, however, can be found plenty of water in all of the regions north of Beersheba. The geological formation and the meteorological conditions of Palestine account for the fact that very little water is retained on the surface of the ground. The surfaces are stony, the stone is mainly dolomite limestone (there is also some flint), so that the rain that comes during the winter soon percolates into fissures or crevices in the stone. Very little of the total rainfall runs directly to the sea; actually no rivers exist in Palestine except the Jordan, which, as is well known, is located in a huge "fault" far below the sea level.

On the western slopes of Palestine it will be a quite easy task to impound water, as the valleys or "wadys" are very steep, forming excellent reservoir sites for collecting the winter rains. The sites must be selected on flintstone formation, or else must be carefully treated so that the water will not escape by percolation into the crevices. One way of treating the slopes of the reservoirs would be to bare the stone surfaces and go over the crevices with a cement gun, thus stopping all the openings through which water can escape.

The climate of Palestine is subtropical, but it seldom rains during seven out of 12 months of the year. Although Palestine during its early history was a prosperous agricultural state, the Turks have simply stripped it of its trees, leaving the whole country a barren waste, as compared with its early reputation of the "Promised Land."

From the very earliest times, the inhabitants of Palestine have been hard pushed to obtain a supply of wholesome water, and possibly no other one physical attribute has so affected the political and religious history of Palestine. History relates how Hezekiah stopped up the outer entrance to the spring, "the Virgin's Font," in order to cut off the water-supply of those besieging Jerusalem, and brought it straight down to the south side of the city of David. The Bible further relates how "Hezekiah prospered in all his works."

Hezekiah carried out what is, to me, one of the most wonderful engineering tasks in history. The tunnel which he constructed stands almost unexplainable today.

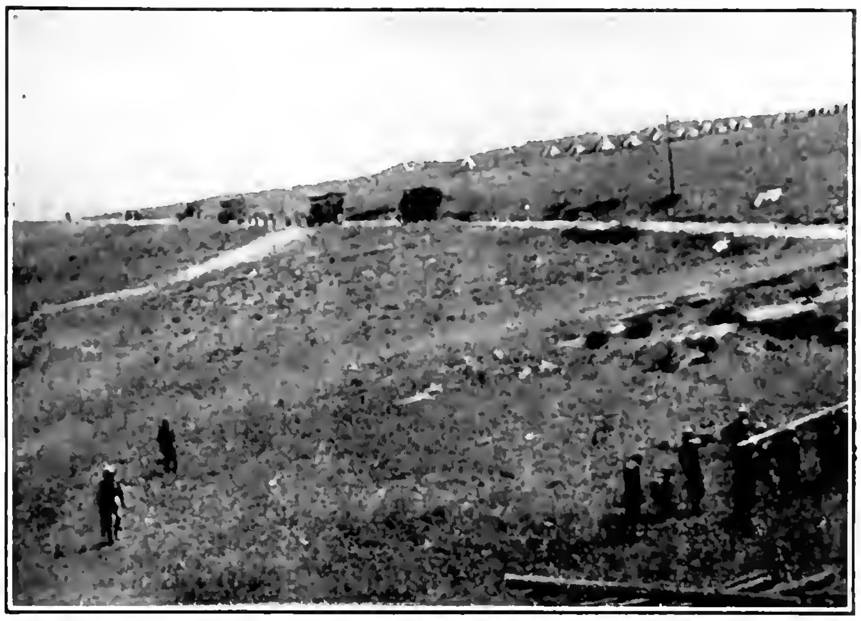


HAIRPIN BEND ON JERUSALEM-RAMLEH ROAD

Illustrating difficulty of transporting materials in Palestine. Caterpillar tractor and two trailers in foreground. Beyond is steep slope of one of the "wadys" which afford possible reservoir sites.

Hezekiah's engineers conducted the water through the limestone hill from the east to the south side by a marvelously built conduit 1750 ft. long. An ancient Hebrew inscription on the west entrance of the tunnel has been translated to read: "The boring. And this was the manner of the boring . . . the pick each toward his fellow . . . boring the hewers struck each to meet his fellow, pick against pick, then went the waters from the issue to the pool for two hundred and a thousand [1200] cubits. . . ." The water flowing in this ancient aqueduct is still used from the Pool of Siloam, which is the terminal point of the tunnel. History seems to indicate that the water was conducted through the hill so that the intermittent spring on the east side of the village could be closed up and all of the water diverted into the Pool of Siloam.

One might easily go on describing the interesting part which water-supply has played in Palestine's history, but suffice it to say that today the land of Canaan needs the modern engineering skill of the West as it needs nothing else, for the development of its water-supply.



PIPE TRANSPORTATION AND LAYING IN PALESTINE
Tractors on Jerusalem-Hebron road hauling pipe for Jerusalem water-supply. Laying 6-inch pipe, in right foreground

its agriculture, its industry and its very place among the modern nations of the world.

Besides Hezekiah other noted men—Solomon, Pontius Pilate and Herod—attempted to get a supply of pure water into Jerusalem, but it remained for the British to do the job in little less than 70 working days. Water is now flowing by gravity through a 6-in. line from the springs at Wady-el-Arub, south of the city, at the rate of over 200,000 gal. per day. The total capacity of the line, which has a delivery head of 200 ft., is 300,000 gal. per day, but the springs have twice this capacity.

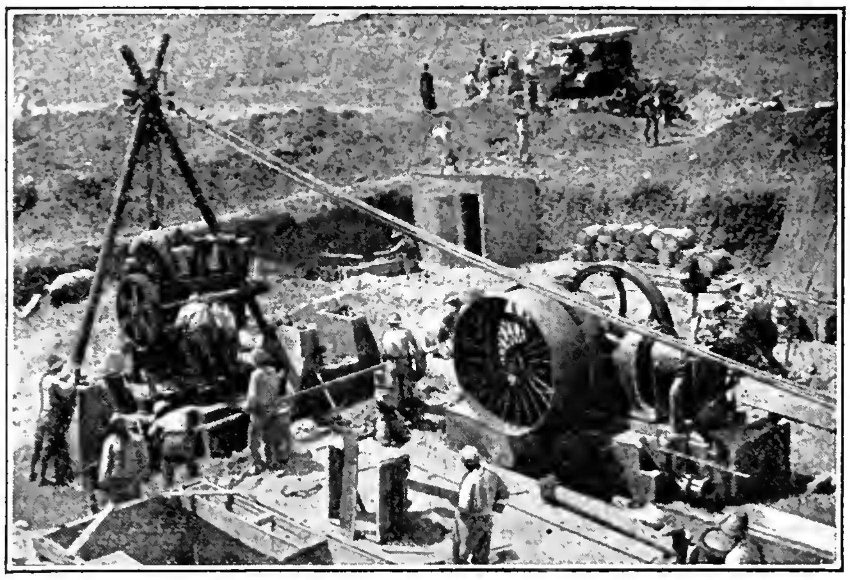
The springs at Arub are located about 16 miles south of Jerusalem, on the Bethlehem road beyond Bethlehem. It was probably Pontius Pilate who carried out with Roman engineers a wonderful piece of work there by developing the spring in the form of a gallery, collecting and conducting the water by aqueduct into a stone reservoir of 5,000,000-gal. capacity located about 2000 ft. from the main spring. Thence Pontius Pilate conducted the water to the center of Jerusalem, probably the temple site, by an aqueduct so marvelously constructed that it stands almost intact to this day. Moreover, the British Royal Engineers found little difficulty

THE LOWER OF THE POOLS OF SOLOMON
The pools have a total impounding capacity of 80,000,000 gallons

in putting the spring and reservoir into service. The water is now elevated by a pump and a 66-hp. gasoline engine into a newly constructed reservoir on the top of a nearby hill. This new reservoir has a position over 500 ft. above the temple site in Jerusalem.

Practically every house has its own rainwater cistern, and it has been estimated that if all these cisterns in Jerusalem were full they would contain 360,000,000 gal. But most of them are usually found to be filthy. One recently inspected by the Sanitary Department had not been emptied for 19 years. Before a cistern is filled with pure water, however, the owner must obtain a certificate from the newly organized health department to prove that his reservoir has been rendered sanitary and mosquito-proof. He is then provided with enough water, through a temporary pipe line, to fill his cistern entirely, regardless of its size. The organized effort to supply pure, sparkling water to the 50,000 residents of Jerusalem has enabled them to have ten times more water than formerly. The picturesque water vendor, with his pigskin pack on his back, likewise the water fantanzies aboard the camel and the donkey, as well as the more charming picture of the native virgin carrying a sheriby (a thin, porous, earthenware jar) on her head, will soon be but a memory of Jerusalem. It is more to be hoped that the terrible water-borne diseases so common when Palestine was under Turkish rule will likewise pass quickly into the forgotten past.

The speed with which British sanitary engineers put



ERECTING PUMPING PLANT FOR JERUSALEM
At Berket-el-Arub, Kilo 23, Hebron road. Two 66-horsepower Hornby engines to lift 300,000 gallons of water under 500-foot head. Caterpillar tractor at work, in background.

into operation this new supply of clear spring water from the vale of Arub will ever stand in engineering annals. A preliminary investigation and survey of the ground was made Feb. 14, 1918, and a scheme was submitted four days later. Owing to the shortage in transport and unusually bad weather, it was not possible to begin work until Apr. 12. Even then the mud interfered with the huge tractors which hauled the many miles of pipe. The pump, which has a working capacity of 300,000 gal. per day under a head of 500 ft., the two 66-hp. gasoline engines brought from Cairo, and the pipe, were in shape for delivering water into Jerusalem by June 18—just 67 days after work commenced.

Jerusalem the Golden could be furnished with an ample supply of pure, sparkling water at a lower cost than it could be done in most American cities. It is possible to supply more than 20,000,000 gal. per day, and this will be sufficient in this country for a population of 1,000,000. In addition to the development of springs at Arub, a similar supply can be had at Wady Kelb, 12 miles distant. At Ain Fowar the winter rains can be impounded and the pools of Solomon can be put into service again with comparative ease.

Water-Waste Education by Bulletins

COINCIDENT with a comprehensive water-waste survey and intensive inspection methods in Buffalo is a campaign of education by bulletins issued periodically by the water department and circulated particularly among the less well informed consumers. The water-saving procedure was described in *Engineering News-Record* of Dec. 5, 1918, p. 1033. The material for the bulletins is taken largely from official records, which are put into easily understood language, with diagrammatic views of such things as the distribution by classes, coal consumed in pumping, water used and wasted, water consumption in other cities—showing Buffalo at the head of the list with its 339 gal. per capita.

One bulletin contains a succinct seven-paragraph description of the water-works system. Another contains instructions for repairing leaky faucets and closets of various types, and presents a table of waste for openings of various sizes. An explanation is made that coal saving during the war became much more than a question of thrift, since the bureau of water, which buys for pumping twice as much coal as either Cleveland or Detroit use, was notified by the Fuel Administration that its coal allotment had been cut from 65,000 tons to 50,000 tons per year. Waste prevention only could effect this saving. This statement was followed with results from eight test meters placed on services with antifreezing toilets, the estimated annual consumption averaging 2,300,000 gal. per year, ranging from 69,000 gal. (one toilet) to 9,580,000 gal. (two toilets). If billed at meter rates the owner of the latter service would have had to pay nearly $400 for his neglect. The regular rate is $1.50 per toilet, although a recent ordinance has raised it to $10 unless an inspection is made and an affidavit filed that the service has been kept in repair. Other points covered are the harm of sprinkling a lawn more than the three hours allotted, and the enormous waste caused by letting water run for cooling purposes.

One incentive to save that is set out is that plans for filters will be started only when the average daily consumption reaches 100,000,000 gal. It is now 124,000,000 gal. and was 163,000,000 gal. in 1917. Bills would be increased by filtration 62% if waste were not stopped, while the people can have filtered water for a 22% increase if the 322-gal. rate is reduced to 175 gal. As the rates decrease that fact is noted and the coöperation of the people is duly recognized.

Just how effective the bulletins are George C. Andrews, commissioner of water, by whom they are issued, is unable to say, but he is sure they give the consumer some understanding of a complicated public utility.

Niagara Falls to Be 100 Per Cent. Metered

FACED with the alternative of spending $500,000 for more filters and additional mains or of placing meters on every service, the Niagara Falls water department has recently decided to become 100% metered. The 3000 meters necessary are now being installed, and would all have been in place June 1 except for a plumbers' strike which threw the work upon the city's own force of two gangs. The installation will be completed this season, but Charles T. Shepard, superintendent, is of the opinion it will take three months before the majority of the consumers realize that they have leaks which must be stopped.

In a report dated Mar. 7, 1918, Mr. Shepard stated that the 16,000,000-gal. normal capacity of the filtration plant had been exceeded on cold winter days of 1917 and that the year's consumption was 26% more than that of 1916. A water-waste examination indicated that the 4000 flat-rate consumers were using 350 gal. per capita daily at a rate about seven times as much as the 3750 metered-service consumers. Manufacturing plants and large buildings consumed 32.9%; domestic services, metered, 6.6%; the city, 10.7%; flat-rate consumers, practically all domestic, plus all other unaccounted for consumption, 49.8 per cent.

Financially considered, 39.4% of the total metered pumpage paid 48.5% of the revenue obtained. This included 6.6% of the domestic metered pumpage, which paid 16.2% of the revenue. The flat-rate consumption and that used by the city produced 51.5% of the revenue. The flat-rate consumers are getting water for the lowest rate, 2.23c. per 1000 gal., which is not profitable, while the total water pumped was sold for 3.657c. The industries pay 3.44c., and metered customers 4.49 cents.

It is estimated that the installation will reduce the annual gross revenue more than $20,000, but the rate of return will be materially increased, and the cost of chemicals and power will be reduced by $4700 per year. The principal saving, however, will be in the 5,250,000 gal. of water, thus putting off for at least five years the time when the works must be enlarged.

Meters are installed by the city at nominal cost to the consumer, a flat charge of $10 being made for each ⅝-in. service. All except about 100 meters will be placed inside the houses. Those in pits, which are being left to the last, will be set at the bottom of an 18-in. tile, 3 ft. long, bell end down, the service pipe being brought up from the usual 5- to 6-ft. depth. A cast-iron cover will be set on the top of the tile and a wooden disk placed on top of the meter, thus creating an air space to prevent freezing. A full-time meter superintendent will be employed, but the number of meter readers will not be increased, the city being redistricted so that the reading will be continuous throughout the year.

New Coal-Handling Plants for Philadelphia Water-Works

General and Detail Design of Three Systems Supplying a Total of 16 Boilers With a Total Boiler Capacity of 7400 Horsepower—Costs Reduced as Compared With Old Methods

By Harrison R. Cady
Bureau of Water, Philadelphia, Penn.

THE Philadelphia water-supply system was completed, in so far as new plants and major projects are concerned, in 1911, when the Queen Lane filtration plant was put in operation. The system now takes an average of 325,000,000 gal. daily from the Delaware and Schuylkill Rivers, filters it, and distributes it over an area of 129 square miles. While the filtration plants are all of comparatively recent construction, some of the pumping stations have been in operation for many years. Consequently, the increase in water consumption, together with deterioration and obsolescence of plant equipment and methods, has necessitated considerable work in the nature of reconstruction and the installation of new equipment. Much work of this kind was done in the four years previous to 1917, but in that year war conditions caused the abandonment of all new work which could be deferred. The more important undertakings include the installation of three complete coal-handling systems, 5400 hp. of boilers, mechanical stokers for 9400 hp. of boilers, 16 pumping units having an aggregate capacity of 195,000,000 gal. per day, and a complete high-tension generating and transmission system furnishing current for lighting and power at five small stations. This article will describe the new coal-handling systems. The general equipment of all five pumping plants is given in the accompanying table.

Belmont—The principal features of the coal-handling system at this station are shown in Fig. 1. About 115 tons of anthracite barley coal are used per day. All shipments are received by rail. Cars are dumped into the storage bins, beneath the tracks, where about 3000 tons can be stored without trimming. The bins have hopper-shaped bottoms leading to gates which feed the cross conveyor, a flight-type apparatus extending through a tunnel under the bins and discharging into a bucket conveyor. This conveyor carries the coal through a branch tunnel to the boiler house, elevates it

EQUIPMENT OF PUMPING STATIONS, PHILADELPHIA

Station	Boilers Number	Boilers Horsepower	Pumps Number	Pumps Horsepower
Belmont	6	3,000	6	6,300
Queen Lane	8	2,400	5	5,600
Shawmont	4	2,000	6	4,500
Torresdale	9	2,950	8	4,000
Lardners Point	14	7,000	13	16,000
Total	41	17,350	38	36,400

and discharges it into the suspended steel bunker in front of the two boilers at the north end. From this bunker, having a capacity of 200 tons, the coal runs down into a 2000-lb. electrically operated weigh larry which distributes it to the stoker hoppers.

In this plant, as well as at the Queen Lane and Shawmont stations, the installation of the conveyor system was coincident with the change from hand-firing to mechanical stokers. Consequently, there is some difference in the point of delivery, a difference which would have worked to the disadvantage of the old system. In the comparative analysis of costs this difference will not be considered.

Under the old system, at Belmont coal was dumped into the same storage bins that are now used, and was trimmed to push cars which were moved on tracks, located substantially as shown in Fig. 1, to firing position in front of the boilers.

The cost of dumping cars and delivering coal to stoker hoppers under the new system is 24c. per long ton. This includes labor, interest, depreciation, maintenance, and power costs. Under the old system, the cost was 29c. per ton under pre-war labor prices, which would mean about 40c. per ton at present labor prices.

Queen Lane — The general location of this station, as related to streets and railroad line, is shown in the sketch plan forming a part of Fig. 2. The other portions of Fig. 2 show the principal features of the coal-handling apparatus and the storage bunker which constitute the new system. This station uses about 100 tons of anthracite barley coal per day, and receives all shipments by rail. The storage bunker, over which cars are placed for dumping, has a capacity of 3200 tons, without

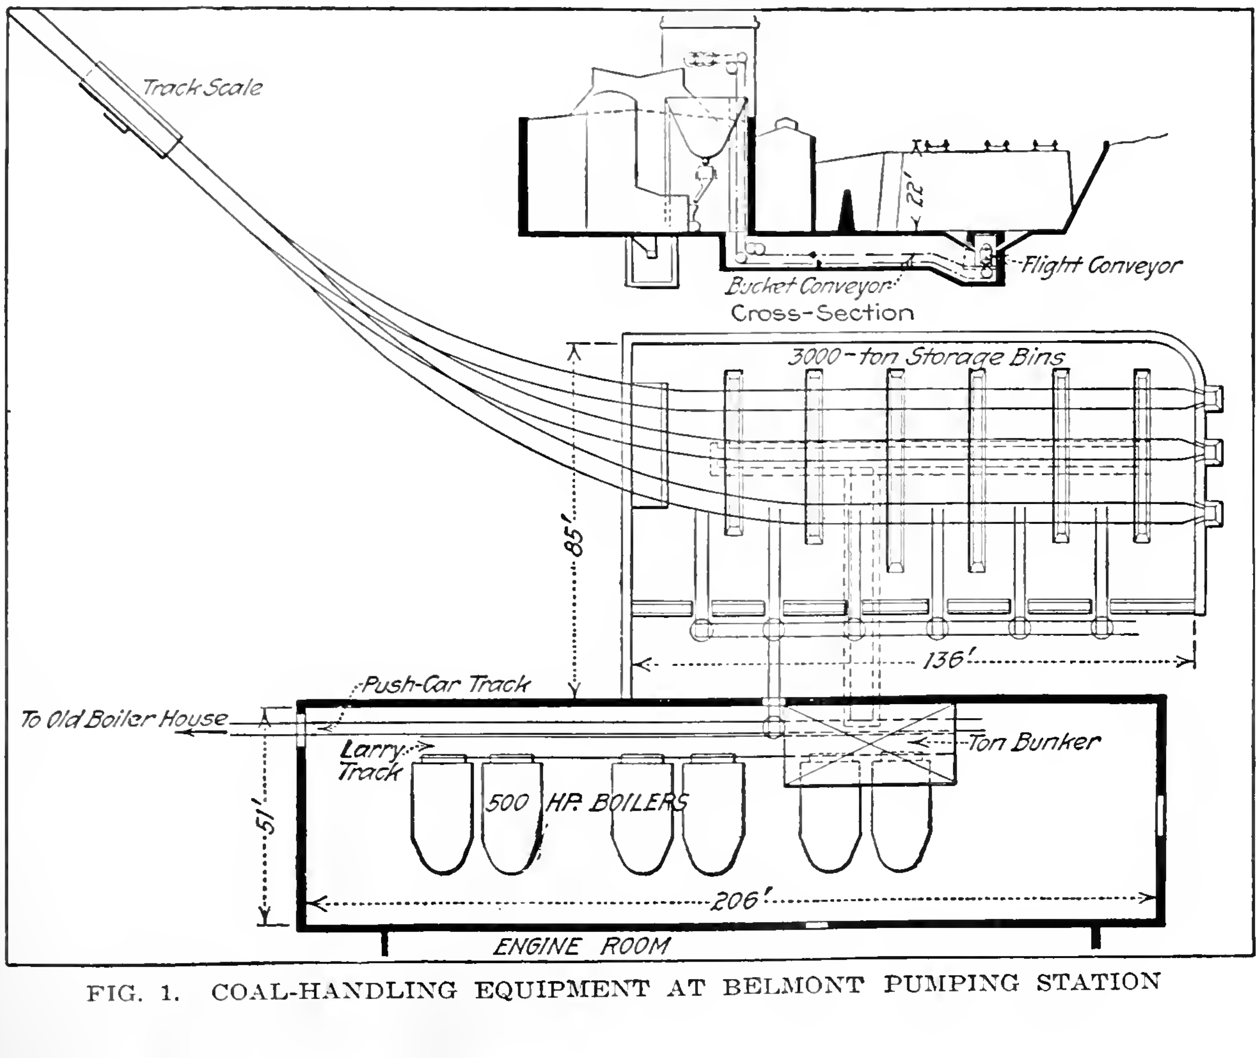


FIG. 1. COAL-HANDLING EQUIPMENT AT BELMONT PUMPING STATION

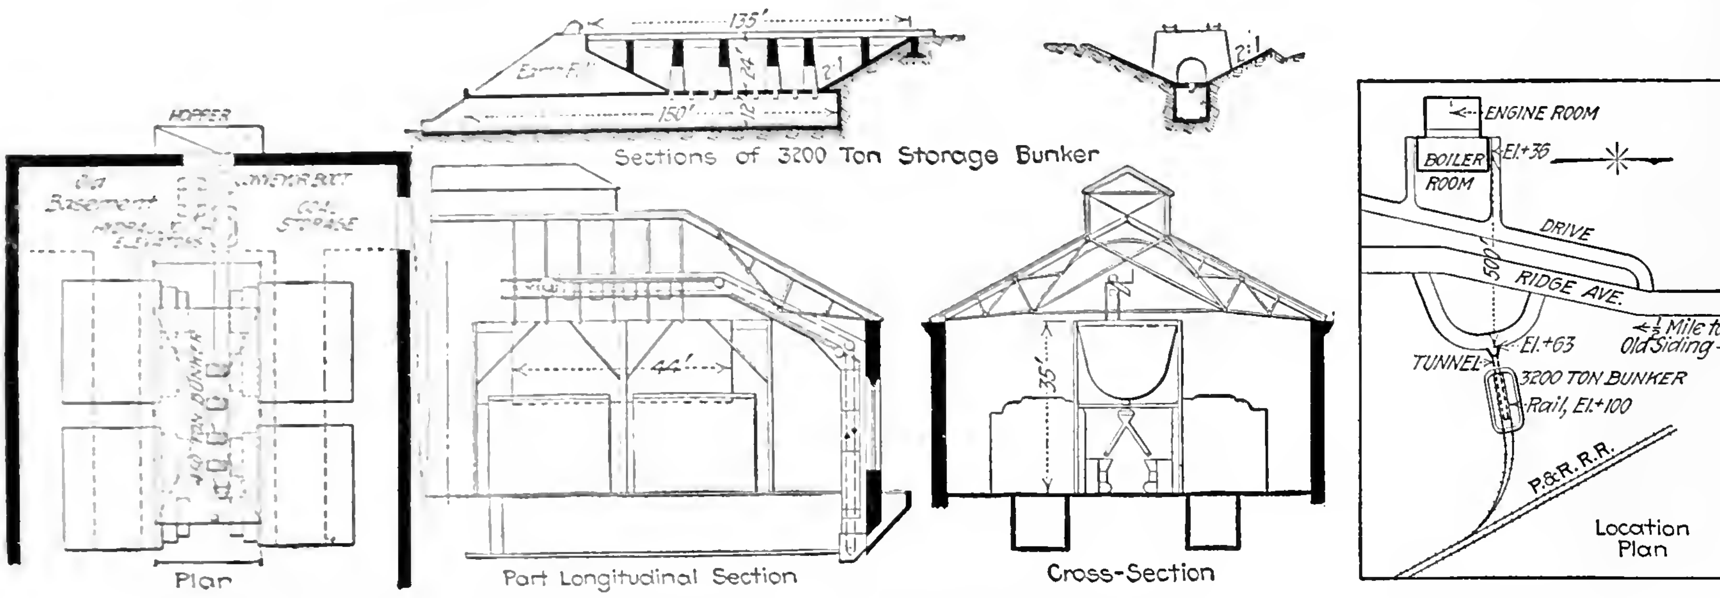

FIG. 2. GENERAL LAYOUT AND DETAILS OF QUEEN LANE STATION COAL-HANDLING PLANT

trimming. From gates at the bottom of this bunker the coal is discharged into motor trucks which haul it to the north end of the station, there dumping into a small hopper feeding a bucket conveyor. This conveyor, which has a capacity of 20 tons per hour, elevates the coal and distributes it along a suspended-type steel bunker of 450-ton capacity. Distribution to stoker hoppers is effected by means of a 1000-lb. hand-operated weigh larry. This larry is found uneconomical here and will be replaced by downspouts in the near future.

Under the old system the coal was hauled from a siding, more than one-half mile distant, where no dumping facilities were available, and it was necessary to shovel from the cars to wagons. The coal was dumped from wagons to bins in the basement at the north end of the boiler room and trimmed to push cars which were brought to the floor level by hydraulic elevators and then moved to firing position in front of the boilers.

At this station the cost of handling from the receiving hopper to stoker hoppers, with the new system, is 23c. per long ton, while the cost of unloading cars, storing and hauling is 24c. per ton, making a total cost of 47c. per ton. Under the old system the cost of handling was about 43c. per ton except when it became necessary to store coal in outside piles, when the cost of recovering was considerably increased. With the old apparatus and present labor prices, the cost per ton would be about 75 cents.

Shawmont — The general layout and details of this station system are shown by Fig. 3. About 70 tons of bituminous coal per day are used here, and all shipments are received by rail. The present coal-handling system was completed in 1916. Cars are dumped into a track hopper, with a capacity of 50 tons, which feeds a double-roll crusher. From the crusher a bucket elevator lifts the crushed coal to the conveyor gallery, where a flight-type conveyor carries it to the boiler room and distributes it in the bunker. This bunker is of the suspended-steel type and has a capacity of 275 tons. Distribution to stoker hoppers is accomplished by means of a 1½-ton motor-operated weigh larry. To provide for cases of delayed or irregular shipments a small storage pile is kept in the old storage shed; the coal from this is brought in push cars to the crusher.

Before the installation of the new system coal was received in the old storage shed which had a capacity of

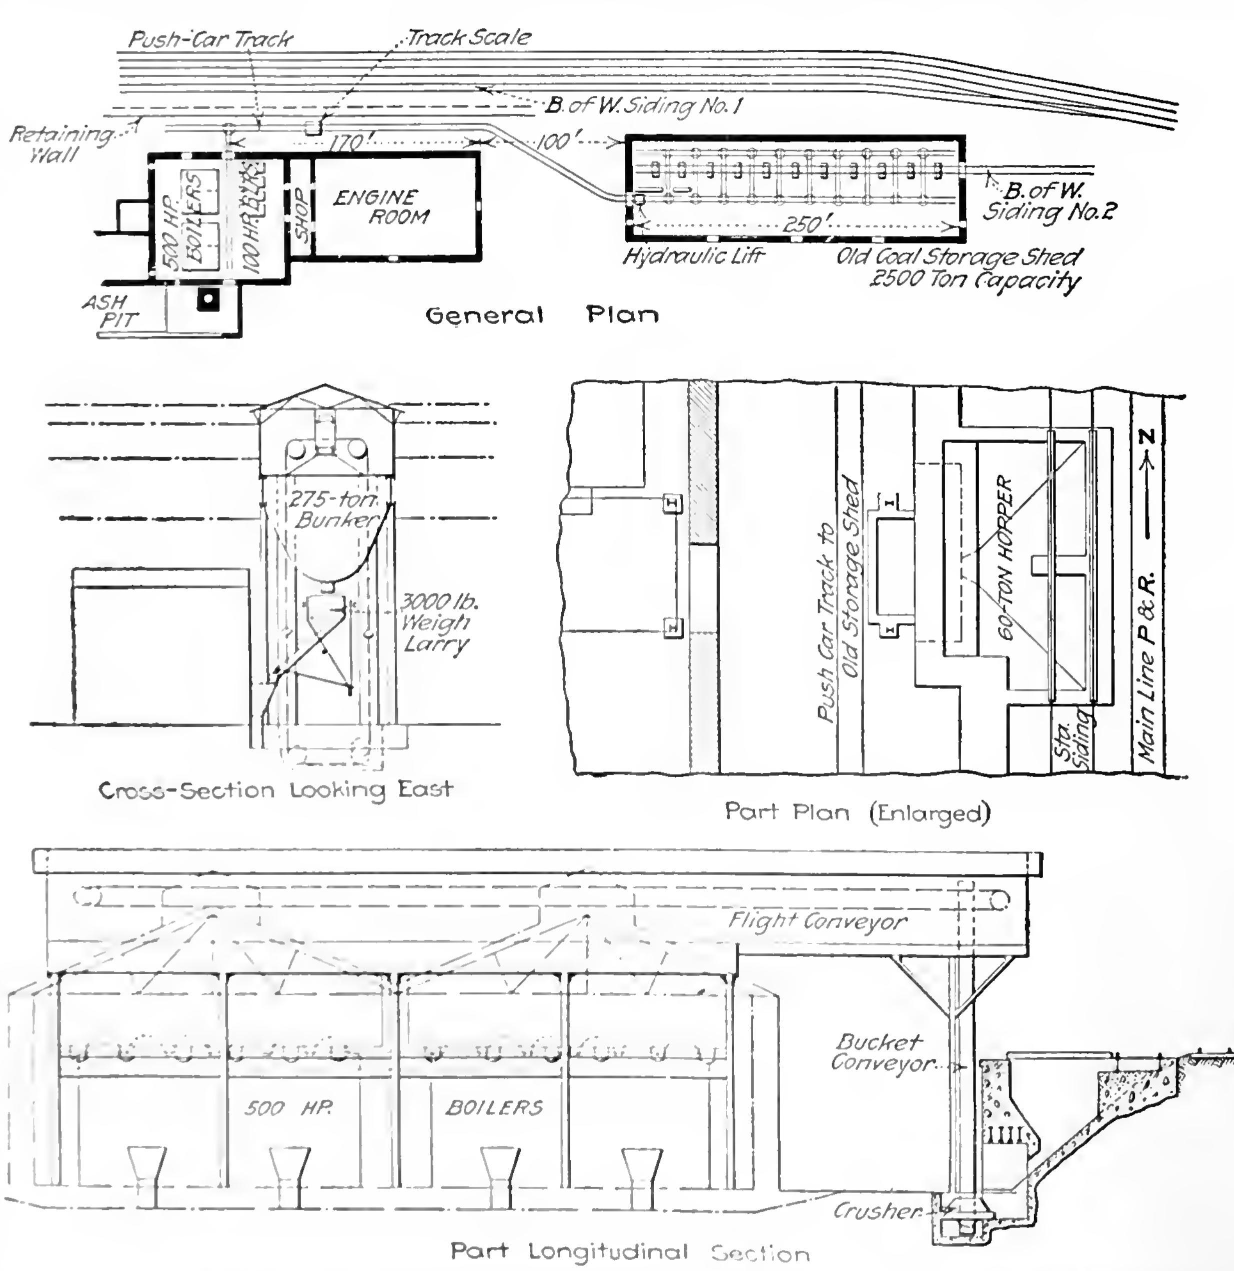

FIG. 3. PLAN AND DETAIL OF COAL-HANDLING PLANT AT SHAWMONT STATION

2500 tons, and was dumped from cars without trimming. The coal was then trimmed to push cars and moved by hand, on tracks shown in the general plan (part of Fig. 3), to the firing aisle in front of the boilers.

The total cost of handling the coal from cars to stoker hoppers and crushing is 24½c. per ton, not including the cost of dumping cars. Adding the latter cost, which amounts to about 8½c. per ton, we have a total cost of 33c. per ton. Under the old system it cost 34c. per ton to handle the coal from the cars to push cars in front of boilers, and increasing this cost to meet present labor prices would make the cost of handling coal now, with the old system, about 44½c. per ton.

To summarize the work of the three systems: In handling a total of 103,300 tons in the past year a saving of $19,150 was effected on the cost of operating the old systems. While this figure may be somewhat reduced in the future, due to lowering of wage scales, it will still remain high, for labor is by far the largest item of cost; and to offset any such reduction there will be certain improvements in operation and apparatus. In addition to the saving in handling costs, to the Queen Lane station has been afforded an easily recoverable reserve storage of 3200 tons, and the Shawmont station has crushing apparatus. The total cost of the three systems was about $54,000, of which the cost of the Queen Lane station's storage and hauling equipment amounted to about $27,000.

Some Engineering Problems of City Planning

Abstracts of papers before the National Conference on City Planning, held at Niagara Falls and Buffalo last week—Regional planning, industrial cities, the steam railroad and the city plan, the common sense of civic centers

Regional and Town Planning

By Thomas Adams

Housing and Town-Planning Adviser of the Canadian Government, Ottawa

TO PLAN our cities and towns properly we must investigate and analyze many problems which have a bearing on life and growth within and surrounding them. Recent tendencies in industrial decentralization have shown the importance of one of the modern aspects of town planning, namely, the direction and control of the growth taking place within the rural and semi-rural districts where new industries are being established. The artificial boundaries of cities are becoming more and more meaningless. The real controlling factors which determine and encourage industrial growth are physical and natural to a greater extent than they are administrative and artificial.

One of the difficulties in dealing with this subject is that we have not yet adopted a clear and unambiguous terminology. Some definitions are in order:

1. *The regional survey* has to do with the investigation and mapping of the existing physical, industrial and residential features of a region that has interests and problems in common, which needs comprehensive and coördinated treatment without regard to arbitrary administrative boundaries.

2. *The regional plan* is concerned with the general planning of the area included in a regional survey. It is a skeleton and tentative plan of a region within which there is comprised a series of municipal units in juxtaposition with one another, and having overlapping and interrelated problems. The width, direction and classification of our main and secondary highways should be governed by the needs of such a region and not by the needs of one municipality within it. This principle is fully recognized in Ontario highway legislation, in regard to the principle on which the cost of construction is apportioned.

The planning of our system of communications in the regional plan should also have regard to the classification of land for different purposes of industry or residence. Land should be classified in a general way for industries, for residences and perhaps for agriculture, for park areas or for special reserves, or as unsuitable for building purposes. We would also consider within the region how far it is desirable to prescribe a code of housing and town-planning regulations to deal with building conditions that need to be dealt with in common over large areas of different character. Sewerage and water-supply may have to be dealt with in large regions to obtain efficient and economical schemes, in cases where it is not practical to get an efficient system of either in separate units of administration. These and other problems that can be dealt with in a preliminary and general way need regional rather than municipal treatments.

3. *The town plan* is the definite plan, accompanying a definite piece of legislation, for fixing within the city or the country areas, first, those parts of a regional plan which are locally approved, and, second, the civic design and regulation dealing more intimately and precisely with the problems connected with the growth of the town, its means of communication, its industrial development, its residential areas, its character and density of building, etc.

We thus have three distinct processes, connected with one another and logically leading up to one another, which are the regional survey, the regional plan and the civic plan. It is unnecessary for me to argue with town planners how hopeless the task is to attempt to prepare a plan without having obtained accurate data regarding existing physical and industrial conditions.

We hear much of reconstruction. One of our greatest needs is to know what and how to reconstruct. In parts of Europe the work of reconstruction is simple and clear. It is a matter of rebuilding what has been destroyed by war. Here, reconstruction has to deal with involved human and economic problems, with transition from disorder to order, with remedies for traffic confusion, and with bad housing and wastefulness of resources. As an English writer recently said, "the monument which this war demands is the reconstruction of the material fabric of civilized life, its reconstruction upon a survey and a plan," and, as Carlyle said long ago, the most effectual of all work of man is wise planning.

It is impossible in this brief paper to analyze the complex problems that need consideration in the regional survey and the regional plan. All that I can

attempt to do is to present some of the reasons why they are necessary and to indicate some of the problems with which they have to deal. I claim that the nature of modern growth of communities, of the relation which exists between different elements in our community life, and the changes which are ever taking place in methods and conditions, impose upon us the obligation to deal with the regulation of growth on elastic principles over wide areas, and at greater expense of time and money than we have hitherto given to it. We must not only prepare our schemes by gradual steps, but prepare them in such a way that gradual fulfilment will be obtained. While our ultimate objective must be clear in our minds, we must be content to work toward it by successive steps instead of jumping to the concluding stages without adequate measures of preparation.

The Niagara district seems to me to be one which needs the making of a regional survey and a regional plan as a preliminary to a series of civic plans for its city, town and county areas. Neither Buffalo nor the Tonawandas nor Niagara Falls is a strategic conter. They are parts of a strategic center of 1000 square miles in extent on both sides of the Niagara River. The problems of this region are international, and give us proof that the power of natural conditions is so great that even the boundaries of nations do not form intelligent and appropriate boundaries to regional and town-planning schemes. Indeed, may we not hope that in the process of planning them we will help to knit these two nations, their industries and people, closer together; and also that the bridge which we propose to erect as a symbol of peace will be more than that, will be a symbol of coöperation and mutual respect? Personally, I should like to see something more than a physical bond; such a bond as could be provided by a regional planning commission representative of the State of New York and the Province of Ontario, to deal with the planning problems of the Niagara district. That need not be an idle dream, any more than the creation of an international waterways commission.

Planning Problems of Industrial Cities

By John Nolen
City Planner, Cambridge, Mass.

The modern city is the industrial city. Most of the planning problems and most of the evils of the modern city are due to manufacturing.

What do we mean by an industrial city? Not a city that is exclusively industrial—few cities are that—but a city that is primarily industrial, a city whose existence and growth depend mainly upon manufacturing. In this sense Bridgeport, Akron, Niagara Falls and many other American cities which are now beginning to grapple seriously with their planning problems are industrial cities.

What are the planning problems of industrial cities? There are two broad divisions, not mutually exclusive by any means, but they can with advantage be considered separately: Those that have to do directly with the economy or efficiency of manufacturing; those that have to do directly with the contentment and welfare of the wage earner, and indirectly (some would say directly) with the economy and efficiency of manufacturing.

The requirements of manufacturing cities are level land, cheap land, few streets (large blocks), room for extension; railroad or water facilities; proper zones; main thoroughfares for hauling (no grade crossings); proximity of factory sites to good housing; trolley or motor-bus transportation for employees if homes are not within walking distance; location of factories with due consideration to prevailing winds; public utilities. Equally important are homes for workmen. Consideration must be given to the house itself; the garden; the protected residential zone; local streets; recreation areas; schools and part-time schools; churches, and main streets to the factory, the low-cost housing and the downtown districts. Consideration must also be given to costs in relation to wages—cost of the home, of living and taxes.

Among the city-planning features of industrial cities may be mentioned especially main thoroughfares, problems in regard to which are connections for goods (factory to freight stations, water terminals, etc.), grade, width, alignment, and freedom from railroad crossings.

What is the difference in the planning of an industrial city and other cities? It is mainly a difference of emphasis of those things which have to do with economy and efficiency in manufacturing, and with the contentment and stability of wage earners. Some of the economic effects of planning upon costs of production are: Proximity to raw material; the elimination of unnecessary cost of hauling and shipping, reduction in labor turnover; and decent living and working conditions both in homes and in factories.

A study of industrial cities discloses the fact that the power, growth and progress of a city are limited only by the initiative of its leaders and the united civic interest of its people.

The challenge to the members of the National Conference on City Planning is, "Do you know of a single industrial city that can claim a reasonable mastery of its planning problems, if tested by the topics here enumerated?" If such cities cannot be named, what are the reasons?

City Planning Handicaps at Niagara Falls

The City of Niagara Falls is at present greatly handicapped in its efforts to obtain an orderly and attractive development by the unfavorable existing conditions, which interfere seriously with its success as a resort, its efficiency as an industrial city, the stability of its property values, and with the growth and increase in wealth of its population.

The removal of these handicaps involves the relocation of the railroad rights-of-way and of the union station, also the elimination of grade crossings (all of which are definitely contemplated), the planning and construction of an appropriate and adequate major street system, the selection and development of a system of parks and parkways, the acquisition of sites suitable for public buildings, schools, etc., and the adoption of an ordinance providing for the separation of city areas for various city needs.

In connection with the rail and water transportation problem, new locations are proposed for the railroad right-of-way, the elimination of grade crossings, the site for a new union station, other railroad development, and the barge-canal terminal and pleasure-boat landing.

The consideration of main thoroughfares includes the selection of existing streets best located for traffic, the extension of existing streets, the locations for new streets, and widenings.

The Steam Railroad in Its Relation to the City Plan

BY EDWIN J. FORT
City Manager, Niagara Falls, N. Y.

TO A very great extent the presence of the railroad determines the character of improvements in its immediate neighborhood, the location of manufacturing industries, development by certain classes of business enterprises, or the poorest class of residences or tenements. The slums and undesirable resorts and the nuisance-producing enterprises are usually not far from the railroad.

When the topographical features of the surrounding territory are such that expansion in every direction is unrestricted, the evils of undesirable railroad location are not so serious, because the city can grow away from them and business can adjust itself, but when, as is the case in Niagara Falls, the site is inclosed upon two sides by an international boundary line and a stream, which so far as the growth of the city is concerned, are impassable, it is most essential to orderly growth and development that the problem of railroad location be given the most careful study and be so worked out that all industries shall be adequately served, that shipping facilities shall be convenient and stations shall be located with due regard for the comparatively large passenger traffic.

We have here [Niagara Falls] no more serious or difficult problem to deal with, in carrying out an acceptable city plan, than that of the treatment of railroads.

Within its comparatively limited area of less than nine square miles, Niagara Falls is crossed from north to south by three surface-railroad lines and from east to west by two such lines. It also has within its corporate limits four separate and distinct extensive railroad yards. The Erie R.R. cuts through what might have been a most desirable residence district, and has its yard at the highest point, almost exactly at the place where the new civic center of the greater municipality is designed to be placed. Obviously, the ideal in the way of a city plan cannot be attained unless some changes are made in those conditions.

There are several alternatives. Lines may be relocated so as entirely to eliminate some of the most objectionable ones. They may be elevated or depressed so as to allow streets to cross at grade, or they may all be allowed to remain as they are, depressing or elevating street crossings where, from time to time, it becomes necessary to do so.

Regardless of what the final plan may be, great relief to every one concerned and considerable advantages to the railroads themselves would come from the electrification of all lines within the limits of the cities located along the Niagara frontier. The abundance of cheap electrical power and the rapid increase in business and population which is taking place should make such a change practicable in the near future.

Such changes as have already been made have consisted in elevating street crossings entirely above the tracks or depressing them below them in such a way as not to disturb the tracks either as to line or grade. These changes add nothing to the embellishment of the city. They are not convenient for street traffic and they are expensive. An indefinite continuation of this method of grade-crossing elimination would result in much haphazard building and in waste of public funds.

If the city is to continue to grow through the development of its enormous resources in power and a corresponding increase in manufacturing industry, the time cannot be far distant when some of the handicaps caused by indiscriminate railroad location must be removed and the districts blighted by them reclaimed.

The Common Sense of Civic Centers

BY NELSON P. LEWIS
Chief Engineer, Board of Estimate and Apportionment, New York City.

AMBITION to create civic centers has become quite general and is laudable. Many projects of this kind have been proposed, some prompted by a desire for the spectacular; others by the hope of realizing some ill defined ideal; some, perhaps, by the prospect of personal gain; and still others through an appreciation of the value of order and economy in public business.

In a study of the civic-center problem the following fundamental principles should control: (1) The centralization of all city business in one locality, while it may result in economy and convenience in the case of a small city, may prove costly and inconvenient in a large city; (2) civic centers should be planned so that only related public business and activities need be concentrated in them, subordinate or secondary centers being established when overcentralization becomes apparent; (3) secondary centers should be so located as to be easily accessible through direct traffic routes from the principal center and from one another, and readily found by those desiring to reach them; (4) the possible need of principal and secondary centers should be kept in mind when developing the plan of any city and its successive additions, so that a rearrangement of the streets about or leading from them may not be necessary; (5) it should be assumed that the buildings comprising the civic group or groups will be worth seeing, and the chief buildings should, therefore, be on the axis of one or more of the streets leading to them; (6) some competent and continuing authority should be required to approve plans for all civic centers and designs for all public buildings or other structures located in or about them, and such plans, once approved, should not be changed without the concurrence and approval of the same authority.

American Engineer to Build Water-Works at Lima, Peru

W. W. Handley, American consul at Lima, Peru, reports that a new water-supply is being designed for the City of Lima by F. W. Spalding, an American engineer now resident in Miraflores, Peru. It is stated the work includes the construction of infiltration galleries for the collection of the water, the necessary aqueducts and distribution reservoirs, and an entirely new cast-iron pipe distribution system, at a total cost of approximately $2,000,000. Work has already been started on the construction of the infiltration galleries and on the reinforced-concrete pressure main. Plans and estimates have also been prepared for a new sewer system and sewage-disposal plant to cost approximately $1,500,000, and a garbage-disposal plant to cost about $150,000. Mr. Spalding was especially engaged by the municipal gov- of Lima to go there and make a report on the various engineering undertakings contemplated.

Highway Design and Construction Papers Read Before Canadian Road Congress

While there were some papers dealing with after-war and the more general roadbuilding conditions, the great majority of the subjects on the program of the sixth Canadian Good Roads Congress dealt with practical problems in the design, construction and maintenance of the various type of country and city highways. The following are abstracts of three of the papers read at the meeting—EDITOR.

Design and Construction of Hot-Mix Asphalt Pavements

BY FRANCIS P. SMITH
Dow & Smith, Consulting Engineers, New York City

HOT-MIX asphaltic pavements, which are distinguished from those of the so-called penetration type by having both the mineral aggregate and the bituminous cement heated and mixed hot, differ from one another chiefly in size and kind of mineral aggregate used, the bituminous cement or binder being substantially the same in each case. The function of the mineral aggregate is to give the requisite amount of stability, while the bituminous cement binds the aggregate and gives pliability to the pavement. It is generally conceded that the ideal surface for mixed traffic is one which is slightly malleable (approaching sheet lead in this respect) as this will minimize wear and noise. This malleability precludes extreme rigidity, hence the malleable pavement will be low in bridging strength and will require a rigid foundation. The ideal pavement, therefore, would appear to be one in which the foundations and wearing surface were separate and composed of materials differing very widely in their properties. All bituminous pavements are, to a certain extent, malleable and yielding; thus the wear of the mineral particles are minimized, and the pavements are made more acceptable for horse-drawn traffic. To obtain the best results, great care should be taken in mixing the surfacing, to get the proper pliability.

FOUNDATIONS

Several different types of foundations have been successfully employed, such as old macadam or telford; broken stone rolled dry or cemented together with some form of bituminous cement; old cobblestones, Belgian blocks or granite pavements; old brick or asphalt-block pavements; bituminous concrete, and natural and portland-cement concrete.

In all of these, stability is the important characteristic. If the foundation is unstable it will sink after the pavement has been put down, and thus will be formed a depression in which water will collect and eventually destroy the pavement. Wheels of vehicles passing over such depressions will drop into them, and the force of the blow will further exaggerate the depression by forcing up a portion of the surfacing. Vibrations in the springs will also be set up, which will cause successive blows to be dealt to the pavement until the springs return to normal. This action, particularly in commercial vehicles, will sooner or later form waves which will be unpleasant to ride over, and which will finally require the resurfacing of the street or road.

The character of the foundation required will depend upon the traffic, the climate, the character of the subsoil, and drainage conditions. The heavier the traffic the stronger must be the foundation. Where traffic is light, the first two types of foundation, named above, may be used. In the opinion of the speaker, telford is preferable to macadam, on account of the larger stones composing its base, which give a partial slab effect. A well drained subgrade is of first importance with this type. In resurfacing, the old macadam surface should be disturbed no more than is necessary to obtain a bond, and the new surface should be reconstructed exactly as if a new macadam road is to be built. Many so-called macadam roads are little more than dirt roads covered with stone and have never been properly drained. In all cases a complete investigation of the history of the road by taking borings and inspections, particularly in the spring, should be made, and provision should be made for draining and rebuilding.

STABILITY IMPORTANT IN BLOCK PAVEMENTS

Old pavements of brick, granite, etc., should not be used as a base if it is first necessary to reset them. In their original condition they are satisfactory, if the traffic is not too heavy. Relaid blocks, until bedded by traffic, are not rigid, and have a tendency to rock, and asphalt pavements laid on such foundations in New York City have rapidly disintegrated wherever they were exposed to heavy traffic.

Bituminous concrete is sometimes employed as a foundation. One of the best types is made of crusher-run stone, from 2-in. down to dust, so graded and mixed with sufficient sand as to make a fairly dense and rigid mixture carrying about 6% of asphalt cement. When it is kept clean after laying and the wearing surface is laid upon it at once, no binder course is necessary. It has less bridging strength than portland-cement concrete, should only be laid on firm, well drained subgrades, and is not suitable for very heavy traffic. It is usually laid from 4 to 6 in. thick. This type has a number of advantages over portland-cement concrete: It is subject only very slightly to expansion and contraction cracks; it binds more strongly with the surfacing, and is also water-repellent, so that underlying moisture will not be drawn up through its pores and attack the bottom of the wearing surface—a frequent cause of disintegration of bituminous pavements laid on cement-concrete foundations.

Portland-cement concrete foundations vary, according to conditions, from 4 to 9 in. in depth, and before they are laid the subsoil should be thoroughly drained and compacted. On certain very heavy clay coils, such as are found in the Northwestern sections of the United States and Canada, which crack and heave very badly in winter, transverse trenches should be dug every 25 or 30 ft. and filled with coarse broken stone. These should be connected and drained to longitudinal trenches at the side of the street, which in turn drain into catch basins. Sand or gravel should then be spread upon the subgrade and compacted to a depth of from 3 to 4 in., and the concrete should be laid upon this instead of the natural soil. Under rapid temperature changes cement-concrete foundations are liable to crack. When the cracks are large the overlying bituminous wearing

surface frequently cracks in or near the same place. Rich, dense concretes are more liable to crack than leaner mixtures, and the speaker advocates a monolithic structure composed of a rather lean mixture, not richer than 1:3:5. Transverse expansion joints in the concrete base to overcome cracking are not altogether satisfactory, as cracks in the surfacing are liable to occur directly over them.

Preparation and Laying of the Wearing Surface

Upon the foundation is placed a wearing surface composed of mineral aggregate and bituminous binder mixed hot. The mineral aggregate constitutes from 80 to 90% of the pavement, and takes practically all the wear resulting from traffic. It must, therefore, be selected with great care. It must be hard enough to carry the traffic; it must have clean grains of particles to insure the adherence of the bitumen to them, and these grains or particles must be graded from coarse to fine, so as to make a pavement of maximum density and with sufficient inherent stability to resist displacement under the shoving action of traffic. Earth, sand, gravel, broken stone or slag, and finely ground limestone or portland cement or combinations of them, are the materials used in hot-mix pavements.

With all these aggregates (with the exception of the earth), the particles should be prefectly clean and free from clay. Material of a flinty nature should be avoided, as the bitumen will not adhere to it. Broken stone is superior to gravel, which should only be used for light traffic and should preferably be crushed. Dense, hard limestone will carry medium and light traffic satisfactorily. Where the traffic, even though comparatively light in volume, is composed of heavy, iron-tired vehicles, a dense hard trap is required. Where slag is used, a dense basic slag is to be preferred. It should be stable when exposed to the weather, and should show no tendency to slack or disintegrate. It is only suitable for light traffic, and should preferably be coated with a very fluid bitumen.

For filler, portland cement is to be preferred for heavy traffic, while ground limestone is preferred by the speaker for light traffic, as it does not have so markedly drying an effect. Whichever is used, it should be ground so that at least 65% of it will pass a 200-mesh sieve. Pulverized clay has also been used with excellent results, but is difficult to handle.

Great care should be taken in mixing the bituminous cement (which should conform to the best standard specifications) with the aggregate. A uniformly good mixture cannot be turned out by an imperfect plant. The best type of plant is that in which the sand or stone, or both, are heated in revolving driers, and fed by means of elevators into a storage bin. Bituminous sand is heated in properly designed melting kettles. The ingredients should be measured or weighed (preferably the latter) and mixed in a twin-shaft mixer of the pug-mill type, which should have a speed of from 65 to 80 r.p.m. For ordinary work each batch should receive a full minute of mixing. It is important to insure a thorough coating of tne surface of all particles with a firmly adherent film of bituminous cement. Great care must always be taken not to overheat either the mineral aggregate or the bituminous cement, as this will injure and harden the latter.

In plants used for constructing pavements made of pulverized earth, the grains after heating are subjected to pulverization, which breaks up any clay balls which may have formed and cleans the sand grains. Owing to the large percentage of water which clay earths are liable to contain, these plants must have a much larger drier than ordinary sheet-asphalt plants. Extreme fineness of the mineral matter necessitates a completely inclosed mixer and measuring box and special dust-collecting devices.

Of the raw materials which have been mentioned, four distinct types of hot-mix pavements are made. They are as follows: Sheet asphalt, Topeka pavement, bituminous-concrete pavement, and pulverized-earth pavements, commonly known as National pavement. The table shows a typical analysis of the types:

TYPICAL ANALYSIS OF VARIOUS TYPES OF HOT-MIX PAVEMENTS

	—Sheet Asphalt— Light Traffic Per Cent.	Heavy Traffic Per Cent.	Topeka Mixture Per Cent.	Bituminous Concrete Per Cent.	Pulverized Earth Pavement Per Cent.
Bitumen	11.0	10.5	8.5	7.0	17.5
Aggregate:					
Passing 200 mesh	14.0	10.5	8.5	5.0	55.5

Sheet asphalt will sustain a very heavy traffic. This statement applies more especially to a traffic largely composed of quick-moving, light, medium-loaded vehicles, such, for instance, as prevails on Fifth Ave., New York City. It is not the most suitable type of pavement for very dense, slow-moving, heavily loaded, iron-tired traffic. Nor will it give satisfaction where there is practically a total absence of traffic, as it then is liable to develop cracks, apparently requiring the kneading action of traffic to equalize the stresses set up by contraction and expansion and to keep it in proper condition. On account of its smoothness, where the traffic is heavy, a 3 to 4% grade is usually considered as the limit for this type, although traffic grades as high as 9 to 12% have been used.

Generally speaking, the heavier the traffic, especially iron-tired traffic, the finer should be the mineral aggregate used. This is because the coarse particles are more liable to fracture than the smaller particles. Where fracture takes place to any considerable extent, rapid deterioration of the pavement will ensue, as the bituminous cement ordinarily used is not sufficiently fluid at atmospheric temperature to rebond and recoat the fractured particles. These will quickly be pulverized and washed out, leaving depressions where water will accumulate and eventually rot the pavement. Where traffic is largely or wholly composed of rubber-tired vehicles, a greater proportion of coarse particles is permissible and is desirable, as it gives greater stability.

Standard sheet-asphalt construction at the present day is 1½ in. of binder and 1½ in. of wearing surface. The binder should be of the "close" type; that is, it should contain approximately 20% of material passing an 8-mesh sieve, and approximately 15% each of ¼-in. and ½-in. stone. A "close" binder properly made and laid will be superior in many respects to the mixtures

that have been laid on a large number of country highways, and will carry a fair amount of traffic for a considerable time without suffering any serious damage. A poor binder will cause serious damage to the pavement. In all hot-mix asphaltic pavements great care should be taken to compress the binder thoroughly, if one is used, with a steam roller, before laying the wearing surface, and, in turn, the wearing surface should be thoroughly compressed.

When the surface mixture is delivered upon the street it should be of such a temperature that it can be properly compressed and should be evenly spread by means of hot iron rakes. In many cases the loads of hot surface-mixture are dumped directly upon the spot where they are to be spread. This is a bad practice, as the men trample upon it while shoveling and raking it, and rakes do not thoroughly loosen up this trampled material when passing over and through it. Although the mixture is raked to a uniform surface of apparently even thickness before it is rolled, those portions which have been trampled on before and during raking are really covered with a greater quantity of surface mixture than those which have not been trampled on. When these spots are rolled there will be a slight unevenness in the finished surface.

Extreme care should be taken to insure a proper union between the work laid on successive days. The first load laid in the morning should be a little hotter than normal, so that the hot mixture may soften the cold edge of the joint. The practice of painting the edge with hot asphaltic cement is not to be recommended, as there is danger of making that portion of the pavement too rich in bitumen and softer.

Topeka Pavement Better with Binder Course

Topeka-mixture pavements are laid from 2 to 3 in. thick, and are frequently placed directly on the foundation. Much better results are obtained by using a binder course 1½ in. thick, with a 1½- or 2-in. wearing surface. This greatly reduces the tendency of finished pavements to shove. With a well graded mixture a squeegee coat is unnecessary, although it is frequently employed. Great care should be taken in mixing these surfacings, and the amount of asphalt must be watched much more closely than is necessary with sheet-asphalt mixtures. One-half of 1% above or below normal is about the permissible variation.

Bituminous-concrete pavements, as previously noted, have a mineral aggregate consisting wholly or largely of stones of varying sizes from 1½ in. down. Some of them are made of crusher-run stone, and some of them (bitulithic, etc.) are made of carefully graded aggregate. Where the aggregates are graded, it is customary to separate the particles of different sizes in from three to five bins, and weigh out definite amounts from each bin for every batch. From 2 to 3 in. of surface mixtures are usually laid directly on the foundation. Pavements of this type will not carry as heavy an iron-tired traffic as will sheet asphalt or Topeka. Both Topeka and bituminous-concrete pavements can be laid upon somewhat steeper grades than sheet asphalt.

Pulverized-earth pavements are usually laid without any binder course, and from 1½ to 2½ in. in thickness. They are very rich in bitumen (15 to 20%), but are extremely stable, and so malleable that at temperatures of 60 to 75° F., a piece may be cut out of them and hammered back with a hammer, and a perfect cold weld obtained. Their stability is due to the extreme fineness and absorbent properties of the mineral aggregate. On account of this fineness it is impossible to wear away the surface by any fracturing or grinding of the individual particles, as they have been reduced to practically their ultimate state of fineness before they are incorporated in the pavement.

The clayey material of which the pavements are composed has a much greater affinity for bitumen than any other known paving material, which still further adds to their permanence. With the exceptions noted under the discussion of plants, their manufacture and laying are very similar to those of sheet asphalt. The cost is somewhat higher than sheet asphalt, owing to the large amount of water frequently obtained in the mineral aggregate which must be dried out, and the high percentage of bitumen used in them. They are capable of carrying the heaviest kind of traffic, and when properly constructed mark less in summer than do sheet-asphalt pavements and are much less susceptible to shoving and displacement. They are equally suitable for very light traffic. The bituminous cement used is about 90 penetration at 77° F., which is much softer than is used in other types of mixed pavement. For this reason they do not become hard, and crack when not subjected to traffic for a considerable time.

Testing Aggregates for Concrete Roads

By H. Eltinge Breed
Consulting Engineer, New York City

Good concrete depends on the quality of the materials—cleanness, hardness, toughness, gradation and proportioning—combined with placing and curing. Methods of testing concrete for road use, chief among which are those for abrasion and impact, are important. Impact tests are by far the most valuable in determining wear-resisting value. Results obtained from a large number of tests made by the New York State Highway Department, with a special machine, seems to justify several conclusions, as follows: (1) Crushed-stone concrete resists impact better than gravel concrete; (2) large-sized materials are more durable than those of small size; (3) toughness is a very important factor in aggregate; (4) the fine and coarse aggregate must both be good, and (5) coarse-grained sand mortar resists impact better than mortar made from fine sand.

First in importance are the materials used; they determine the quality of the pavement. The fine aggregate should be tested for: (1) organic impurities, by the colorimetric test; (2) gradation (sieve analysis); (3) mortar strength, by testing briquettes; (4) volume of silt or loam by measurement. These are all field tests, except the third, and are very valuable.

The coarse aggregate cannot be tested in the field. Field determination of these materials can be made only for voids. Visual inspection should, of course, detect soft material and dirty aggregates. Such inspection should be made constantly, to know that the material is running uniform and of quality equal to the original sample.

For laboratory test of coarse aggregates, the most valuable is the Deval abrasion test. It is in general use and has been standardized. How accurate it is in determining the suitability of coarse aggregate for con-

crete remains to be seen. It is certain, however, that this test indicates the difference between poor and good stone; and, taken in conjunction with the impact test, described later, it is the best means we yet have of determining the suitability of stone for concrete roads.

Tests for pebbles (called gravel by some) with the Deval machine have been unsatisfactory, because certain pebbles much inferior in service to trap and syenite rock show less loss when tested than do these standard materials. In 1915 the New York State Highway Department laboratory modified the Deval stone-abrasion machine by substituting a slotted cylinder for the closed cylinder. The slots allow the fines to escape, so there is no protective cushion of dust to keep the pebbles from wear. For four years we found that this machine has given slag and pebbles a truer rating in accordance with the service test, though often at variance with the showing of the standard cylinder.

After testing the aggregates, we made tests of the resulting concrete, for two purposes: (1) To determine its wear; (2) to determine its strength.

By far the most valuable test to determine the wear-resisting values is a machine which generates impact stresses, closely paralleling those imposed by traffic. This machine was described in *Engineering News-Record*, of May 2, 1918, p. 861, by H. S. Mattimore, engineer in charge of physical testing, New York State Commission of Highways. In general, the machine consists of an arm which is raised by a cam and falls freely, striking a 6-in. concrete cube or cylinder upon a table which is revolved by a dog attachment. At the head of the arm are placed nine hitting points, armored with nonslip horse calks, each point and its shaft being held in place by a spring giving a play of ½ in. to compensate for any irregularity or unequal wear. The effective weight of the head is 29 lb., and the blows are delivered at the rate of 100 per minute. The blows of the calks strike in nine concentric circles ¼ in. apart. To date, several hundred tests have been made with this machine. The reports in the table are representative.

PARTIAL RECORD OF IMPACT TESTS MADE BY THE NEW YORK STATE COMMISSION OF HIGHWAYS

Coarse Aggregate	Fine Aggregate	Mix	No.	Grams Lost per Test	Average Loss	Remarks
Trap	Sand, Niagara	1 : 1½ : 3	3	150-110 105-95	103	Small stone area omitted
Trap	Sand, Cowbay	1 : 1½ : 3	4	110-120 110-100	110	
Trap	Sand, Albany	1 : 1½ : 3	4	140-100 125-125	122	
Trap	Sand, Long Island	1 : 1½ : 3	2	120-135	127	
Trap	Sand, Marlboro	1 : 1½ : 3	2	130-135	132	
Trap	Tailings, graphite	1 : 1½ : 3	2	155-135	145	
Trap	Sand, Booneville	1 : 1½ : 3	4	165-130 165-135	149	Group (1) 103-165
Trap	Tailings, iron ore	1 : 1½ : 3	5	200-155 165-155 165-180	164	Excess grout omitted
Trap	Sand, Cowbay	1 : 2 : 4	2	150-150	150	Group (2) 150-175
Trap	Sand, Albany	1 : 2 : 4	3	180-160 185-225	175	Small stone area—excess grout omitted
Trap	Sand, Marlboro	1 : 2 : 4	2	180-170	175	
Syenite	Sand, Booneville	1 : 1½ : 3	8	150-145 150-140 145-125 185-130	141	Group (3) small stone area omitted 141-186
Syenite	Sand, Booneville	1 : 2 : 4	4	180-205 180-180	186	
Buffalo Limestone	Sand, Niagara	1 : 1½ : 3	5	150-120 155-125 135	137	Group (4) 137-170
Buffalo Limestone	Sand, Cattaraugus	1 : 1½ : 3	5	155-160 140-125 160-200	148	Excess grout omitted
Buffalo Limestone	Sand, Booneville	0 : 1½ : 3	4	180-160 185-160	171	

The results indicate that generally the average loss increases as the mortar strength of the sand decreases. An average loss for each test shows that there is greater strength in the 1 : 1½ : 3 mix than in the 1 : 2 : 4 mix. It is interesting to note that syenite, with a French coefficient of 12.5, shows, approximately, an equal loss under this test with Buffalo limestone with a French coefficient of 7.9. On the basis of the Deval test, the limestone is inferior for road purposes to the syenite, but service conditions indicate that the Buffalo limestone and many other limestones, with a French coefficient of 7 and better, are very satisfactory in service.

In the test to indicate strength, concrete from a batch is made up on the road into 6-in. cubes or 6 x 12-in. cylinders from every 500 cu.yd. or less of material. They are cured for 21 days in moist sand and then shipped into the laboratory and tested at 28 days. The following is a record of four years' work:

Years	Mix	Coarse aggregate	No. of cubes	Average compression per square inch
1915-16	1 : 1½ : 3	Stone	1684	3590
1917-18		Gravel	221	2950

It may be noted that a total of 1905 tests were made and that, with the exception of the gravel, they are well over 3000 lb. per square inch. When any individual test shows below 3000 lb., a thorough investigation was immediately made to determine the cause. While this occurred too late to correct the given piece of work, it had a good moral effect on the contractor, and a wholesome rivalry was inspired among the engineers to have a high test value for their work. The figures given above represent actual tests from the laying of something over 400 miles of 16-ft. concrete pavements of 6-in. average thickness.

Factors Influencing the Selection of Road Plant

By Arthur H. Blanchard
Consulting Highway Engineer, New York City

HIGH wages for unskilled labor in 1917, 1918 and 1919, and the uncertain status of the labor supply of the future, have resulted in a thorough analysis of highway-construction data to determine economical methods of using road machinery. In the opinion of the writer, American highway officials must face high wages for unskilled labor for several years. It is not logical to expect that unskilled labor which entered the service will rush back to the pick and shovel after demobilization. Emigration records show that thousands of laborers are leaving America every month. Immigration, the usual source of supply of unskilled labor, is an unknown quantity. It is not surprising, therefore, that the reconstruction period finds highway officials, engineers and contractors investigating all types of labor-saving machinery.

Selection of Equipment

The selection of equipment for the construction and maintenance of highways should be based upon a consideration of the following factors: (1) Character of work; (2) specification requirements covering equipment; (3) amount of work; (4) portability of plant; (5) large and small units; (6) ease of manipulation; (7) adaptability to different classes of work; (8) funds available; (9) depreciation of plant; (10) transporta-

tion facilities. The practical necessity for the consideration of many of the above factors is self-evident.

Character of Work—In the case of contractors whose work is confined to the construction of sheet-asphalt pavements, and in the case of a department such as, for instance, that of Wayne County, Michigan, where the highway work consists primarily of grading operations and the construction of cement-concrete pavements, the problem is materially simplified. On the other hand, where a contractor's work covers the construction of the various types of roads and pavements used in a municipality, county or state, the selection of the several units of plant equipment should be based upon their adaptability to different classes of work.

Specification Requirements Covering Equipment—In the modern practice of highway engineering, many specifications include stipulations which must be met by the machines and accessories employed. Illustrations might be cited such as the weight of rollers, pressure limitations in distributors, grouting apparatus, and detals of mixers for the manufacture of bituminous concrete.

Amount of Work, Portability of Plant, Large and Small Units—It is evident that a contractor for a department will be justified in the purchase of an ideal equipment if the work is to be extensive in character. If the work is centralized and large in amount, as in the case of sheet-asphalt work in many municipalities, a large, well equipped, permanent plant will prove economical. If, on the other hand, the work is large in amount but distributed over considerable area, small, portable units will prove more satisfactory, as in the case of mixing plants for the manufacture of bituminous concrete to be laid on country highways.

Ease of Manipulation—In cases where contractors are engaged in general highway work and their organization does not include foremen who are specialists in the manipulation of various types of complicated machinery, it is of the utmost importance that simplicity of machines and ease of manipulation should receive great weight, in the selection of equipment. This is particularly true in connection with various types of machines used in the construction of bituminous surfaces, bituminous-macadam and bituminous-concrete pavements.

Adaptability to Different Classes of Work—It is well known that specifications for different classes of work, requiring the same type of machine, call for differences in detail. For grading work, specifications might require rollers weighing from 12 to 15 tons, while in the construction of wearing courses of some types of pavements a 10- to 12-ton roller is stipulated. A contractor who is handling a small amount of general highway work would find it advantageous, therefore, to purchase a 12-ton roller suitable for both classes of work.

Funds Available—Departments and contractors are necessarily forced to consider first cost of equipment, as the funds available may not permit the installation of the most economical and efficient machines. In many cases where such conditions are encountered it is obvious that it will not be practicable to anticipate that the work can be accomplished with the same degree of rapidity and at the same cost as if more efficient machinery were available.

Depreciation of Plant—Depreciation charges on plant should receive careful consideration, prior to the purchase of machines and accessories, as well as in the consideration of the cost of highway work.

Transportation Facilities—Facilities for the transportation of machinery and materials affect materially the efficiency of the several units of plant. For example, in municipalities, states and provinces where materials may be transported over highways in good condition, the use of the motor truck will usually be found desirable.

Filter Operations at Niagara Falls

OPERATING costs of the Niagara Falls municipal filter plant for the year 1918, taken from the annual report of B. T. Dignan, chemist in charge, indicate low unit costs. This rapid filter plant, which has a nominal capacity of 16,000,000 gal. daily, was described on p. 601 of *Engineering Record*, of June 1, 1912, the year of its completion.

For 1918 the bacterial count by months averaged 14, with high and low figures of 33 and 6. The removal ranged from 99.47% in December to 99.90% in January.

SEVEN YEARS' MECHANICAL FILTER OPERATING DATA AT NIAGARA FALLS, N. Y.

Year	Hypochlorite	Cost per 1,000,000 Gallons Alum	Power	Labor	Total
1912	$0.00	$1.79	$1.82	$2.12	$5.73
1913	.04	1.25	1.97	2.46	5.72
1914	.10	1.00	2.16	2.99	6.25
1915	.08	1.10	2.38	3.73	7.29
1916	.25	.75	2.37	3.62	6.99
1917	.21	.75	2.14	3.16	6.26
1918	.14	.86	2.13	3.05	6.18
Average	$0.12	$1.07	$2.14	$3.02	$6.35

Bacterial Results, Alum Dose, Hypochlorite Rates and Typhoid Figures

Year	Bacteria per cc. on Gelatine	Per Cent. Bacteria Removed	Alum, Grains per Gal.	Price of Hypo. per lb. in. N. Y.	Total Cases	Typhoid Deaths
1912	34	98.41	1.25	0.00	66	23
1913	32	98.71	0.87	2.67	26	10
1914	25	99.27	0.70	6.61	17	6
1915	12	99.62	0.77	5.02	10	0
1916	26	99.49	0.52	4.18	16	5
1917	15	99.69	0.41	4.35	13	3
1918	14	99.76	0.40	4.00	15	2
Average,	22.5	99.28	0.70	4.30		

Likewise, the variation in chemical-treatment cost varied only from $0.88 in October to $1.06 in February. Wash-water percentages varied from 1.16% in August to 2.74% in June, the higher figure being due to algæ growths in the lake shortening the runs. The average for the year was 2.05 per cent.

The typhoid situation has not changed from the enviable position held by the city, as noted by Charles B. Burdick in *Engineering News-Record* of Sept. 6, 1917, p. 440. It is pertinent to add that the Niagara River is continuously polluted by the raw sewage of 500,000 persons in Buffalo, 20 miles distant; also, that the municipal plant does not furnish all of the water to the city, but that the Western New York Water Co. supplies about 7,000,000 gal. daily of filtered and disinfected water to manufacturers and to 700 domestic consumers.

Kansas Water-Supplies To Be Studied

Research work planned by the Kansas State Board of Health includes water-works operation—particularly as to plants treating surface waters, swimming pools, sewage-disposal and the control of pollution of water-supplies by oil wells. F. M. Veatch is acting engineer of the division of water and sewage.

Women Water-Waste Inspectors at Baltimore, Maryland

Men Replaced With Satisfactory Results—Women Under Direction of Pitometer Engineer Paid $2.76 a Day

By Walter E. Lee
Water Engineer, Baltimore, Md.

WOMEN inspectors have taken the place of house-to-house men inspectors, for a year past, in the water-conservation campaign which is a part of the daily operation of the Baltimore Water Department.

The main campaign is based on pitometer surveys of consumption and leakage occurring on underground mains and services. Preceding the pitometer measurements, all leaks on plumbing in buildings are eliminated or repaired and stop-cocks on house service pipes are made tight, to cut off all demands effectively. This includes the overhauling of house service pipes, stop-cocks and boxes by construction gangs and house-to-house inspection of plumbing and sanitary fixtures in the district under investigation, by women inspectors working under the direction of a pitometer engineer. From the time water conservation was started in 1914 until Apr. 1, 1918, male inspectors were employed, averaging 50 to 100 inspections each per day, depending upon the character of the leakage found. The results obtained through the male inspectors were not altogether satisfactory, and, due to the effectiveness of women inspectors on mosquito-prevention work, it was decided to employ the same women permanently the year round, on house-to-house inspection.

INSPECTRESS LISTENING FOR WATER WASTE

The women inspectors are selected and employed on the basis of fitness, preferably between the ages of 30 and 45, and they must have good hearing to enable them to use the aquaphone in detecting wasting water on house-service pipes and plumbing. They must be neat in dress, quiet, mannerly and able to make direct replies to interrogations.

Each inspectress is equipped with an aquaphone for detecting water flow in the plumbing, a flashlight for use in cellars and basements, a street directory for the location of her daily assignment, and a stiff-back book holding her daily report sheets. The entire equipment is contained in a stiff leather case.

The hours of employment are from 8:30 a.m. to 5 p.m. five days in the week and to 3 p.m. on Saturdays, with one-half hour for lunch. The wage is $2.76 a day, or $16.56 a week. Twenty inspectresses are to be ultimately employed.

WATER DEPARTMENT CITY OF BALTIMORE
ENGINEERING AND CONSTRUCTION DIVISION.
S. W. Cor Oliver and Wolfe Sts

Date March 27 1919

To the occupant and to the owner of 600 E 42nd St

Notice is given that there is waste of water in the above premises due to leaking spigot in kitchen

If not repaired as required by law (City Code 1906, Art. 40) in 7 days, the water will be turned off.

Served by Mrs C.B. Stewart Inspector. WALTER E. LEE, Water Engineer.

Received by Mrs. E. M. Brown on premises.

1086-1-18-19-A Co.-100 B-200 L.

WATER WASTE NOTICE SERVED ON CONSUMERS
Original slip 4⅜ by 3⅜ inches, thin paper

A year's experience demonstrates that results are better than with men inspectors, for in such house-to-house inspection a municipality must always deal with the housewife or maid servant, and women inspectors can better educate them as to the object of the survey.

When water waste is found on any premises inspected, either through a split service pipe or a leaking plumbing fixture, a notice is served on the occupant of the premises and a reinspection is made one week from the serving of the notice, to see whether repairs have been made.

NOTE:—WHEN TRANSFERRING SHEET FROM BOOK TO FILE CUT OFF MARGIN

CONTINUOUS RECORD FOR WATER-WASTE INSPECTIONS
Original, 5 by 6 inches on thin paper, with duplicate on reverse side

A schedule of house-to-house inspection is arranged so that each property receives about three inspections a year, and provision for subsequent inspections is provided for on the report sheet showing the style of the fixture that is leaking and its location on the premises.

The Numerical Interpretation of Bacteriological Tests

Theory of Probabilities Applied to Sanitary Engineering, With Particular Reference to Results Obtained in Studies of Water and Sewage

By Milton F. Stein
Civil Engineer, Chicago, Ill.

IT IS a peculiarity of the human mind that in any comparison other than the most elemental there is always an urgent desire to resort to the use of numbers. This holds true in the case of bacterial work, as is evidenced by the various attempts to express the complex bacterial characteristics of a water or sewage by a single index number. It is highly desirable, for purposes of comparison and standardization, that such results be numerically expressed, and it is the purpose of this article to explain the proper methods of numerical interpretation and to point out certain conditions which must be met, and certain limitations which must be submitted to. The methods given are based on the theory of statistics and probabilities. It is not intended to explain the underlying theories, which have been fully developed elsewhere, as given in the references, but simply to state the principles involved and to show their practical application.

To avoid confusion it may be well to define the use which will be made, for the purpose of this article, of certain terms commonly used indiscriminately:

By a *sample* will be meant the quantity of liquor, removed from the main body thereof for testing purposes, and which may be of any size, from the usual bacterial sample to one or more gallons.

By a *test* will be meant the operations involved in developing and counting the colonies on a single plate, or in producing and recording a result in a single fermentation tube. Thus, a *sample* may be subjected to but one *test* or to a number of *tests*. The *quantity tested* will refer to the amount involved in each test—10 cc., 1 cc., 0.1 cc. or other fractional part, this quantity being often called the *size of sample.*

There are evidently two kinds of bacterial results to be considered: (a) Those based on a *single sample,* such as would be made on the same portion of a liquor at each of the several steps in a continuous process of purification, to determine the changes or improvement effected, or on a definite, limited quantity of liquor to determine its bacterial condition; (b) those based on *repeated samples,* such as routine results obtained from day to day in filtration plants and sewage-disposal works.

There are two types of tests usually made: (a) *Numerical tests,* such as the usual bacterial count; (b) *tests of attributes,* involving the presence or absence of some one attribute or characteristic, as the presence or absence of gas in the fermentation test used in the detection of the colon bacillus in water.

Arithmetic Mean the Best Average—In averaging a number of tests, either on a single sample or on repeated samples, the ordinary arithmetic mean gives the most logical result, being rigidly defined and based on all the tests made. Its significance is readily comprehensible and it lends itself to simple computations. The use of the median, or the middlemost value of a series when these are arranged in the order of their magnitude, has been proposed, because in it the effect of exceptionally large and small values upon the average are partially neutralized, but no reasons have been advanced why such divergent values are entitled to less consideration than the rest. The geometric mean has some advantages in special cases, but its nature is not generally understood, and its calculation is rather involved.

The Expected Error—The expected error is sufficiently defined by its name. The formulas for it are derived by means of the theory of probabilities, assuming certain ideal conditions to exist. As applied to bacteriological tests these conditions would be:

1. That all bacteria in the liquor sampled are identical in all characteristics affecting the results of the tests, such as rate of growth, vitality, effect of environment, etc.

2. That, in single samples, the distribution is essentially uniform, and, in repeated samples, the number in the liquor does not vary from sample to sample.

3. That all the bacteria are independent, in the sense that one does not hinder the development of another by overgrowths, toxic products, etc.

In the conventional interpretation of the bacterial count these conditions are assumed to obtain, in that no allowance is made for unequal distribution of bacteria in the liquor, and all the bacteria plated are supposed to produce visible colonies within a specified time and without mutual interference. We know that such an ideal state of affairs does not hold, and it is one of the tasks of the statistical method to devise a measure of departure therefrom.

The rules for finding the expected error are:

1. The expected error in the number of colonies on a single plate is equal to the square root of that number. If a dilution is used in the test, then the expected error in bacteria per cubic centimeter is obtained by multiplying the square root of the plate count by the dilution factor, just as the plate count must be multiplied by the dilution factor to give the bacteria per cubic centimeter.

2. The expected error in the number of colonies on any plate of a series made from the same sample is equal to the square root of the arithmetic mean number of colonies per plate in the series. Here, again, results must be multiplied by the dilution factor to apply to bacteria per cubic centimeter.

The general formula (See Stein, "A Critical Study of the Bacterial Count," in *American Public Health Journal* of November, 1918) for these rules is:

$$\varepsilon(\alpha) = \sqrt{\frac{\alpha}{n}}$$

$\varepsilon(\alpha)$ = The expected error in the number of bacteria per cubic centimeter in any one test.

α = The number of bacteria per cubic centimeter as determined by a single test, or, better, by the mean of a number of tests.

n = The dilution factor, 10, 100, 10,000, etc., as the case may be.

Theoretically, α should be the actual number of bacteria per cubic centimeter, but since this is not known exactly, the best value available should be used, which is the mean of the available tests.

The expected error of the mean of a series of tests is obtained by dividing the expected error for a single test by the square root of the number of tests in the series, or

$$\varepsilon\,(M) = \frac{\varepsilon\,(a)}{\sqrt{N}}$$

M = The mean number of bacteria per cubic centimeter.

N = The number of tests in the series.

THE STANDARD DEVIATION—If a number of tests are made on the same sample the results will in general differ among themselves and also from the arithmetic mean. Some measure of this deviation from the mean is necessary in order to establish the accuracy of the latter quantity. If, following a natural and logical impulse, we attempt to find the mean value of these deviations, with due regard to signs, we are baffled by the result, which is invariably zero. It is therefore customary first to square these deviations, which at once eliminates the difficulty of signs, then to find the mean, and extract the square root thereof.

The result is called the *standard deviation.*

It may be formulated as follows:

$$\delta = \sqrt{\frac{(a_1 - M)^2 + (a_2 - M)^2 + \ldots . (a_N - M)^2}{N}}$$

δ = The standard deviation.

$a_1\,a_2\,\ldots a_n$ = Bacteria per cubic centimeter as determined by the different tests.

M = Mean value of bacteria per cubic centimeter.

N = Number of tests made.

There are good theoretic reasons for the use of the standard deviation as a measure of dispersion, not the least of these being that, under the ideal conditions given previously, it is equal to the expected error.

The standard deviation or "mean error" of the mean is given by the formula,

$$\delta_M = \delta/\sqrt{N}$$

THE LEXIAN RATIO—Since, under the ideal conditions, tacitly assumed in the bacteria count, the standard deviation is equal to the expected error, the ratio of the former to the latter is a measure of the departure from these ideal conditions. This is known as the Lexian ratio, and is given by the formula $L = \delta/\varepsilon$.

If the conditions are "normal," as assumed, this ratio will be equal to 1. If the distribution of bacteria is irregular, and the usual small accidents and interferences in plating and counting occur, the Lexian ratio will be greater than 1.

APPLICATION TO THE BACTERIAL COUNT—*I. The Single Sample; a. Single Test*: In Fig. 1 the expected errors in a single test for various numbers of bacteria per cubic centimeter are shown for tests of 1-cc. quantities. For other dilutions multiply the expected error as shown on the diagram by the dilution factor. *Example:*

A single plating of a sewage sample at 10,000 dilution gives a count of 256 colonies. This is equivalent to 256 × 10,000, or 2,560,000 bacteria per cubic centimeter. From Fig. 1 the expected error for 256 is 16, which multiplied by 10,000 gives an expected error of 160,000 bacteria per cubic centimeter. The largest error which may be reasonably expected is three times the expected error, in this case 480,000 per cubic centimeter.

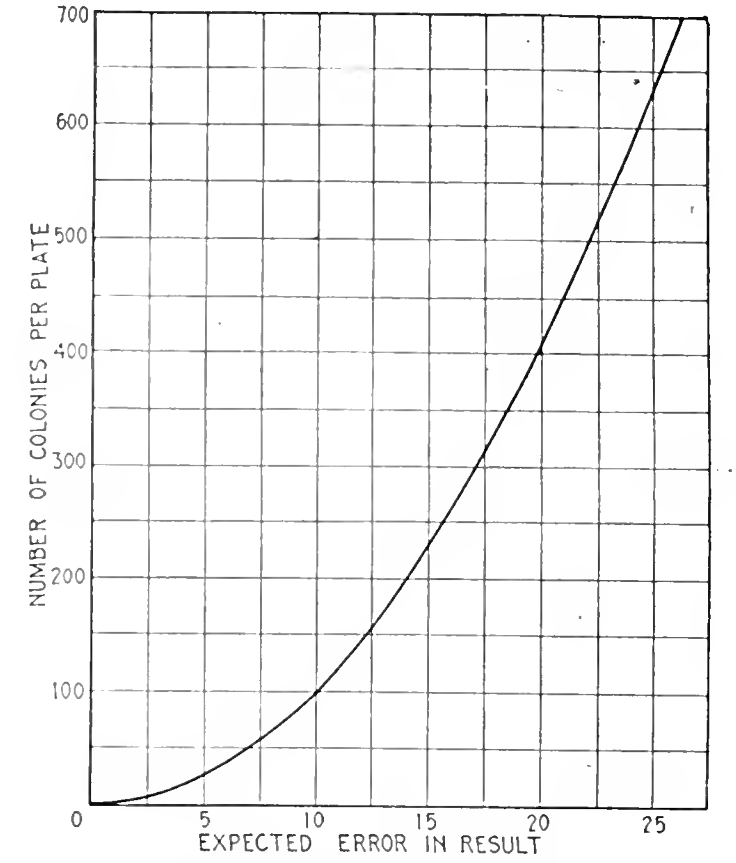

FIG. 1. CURVE SHOWING EXPECTED ERROR IN BACTERIAL COUNTS

Fig. 2 shows the expected error in per cent. for various numbers of colonies per plate, and may be called a *precision curve.* It shows very clearly that *to reduce errors in the bacterial count, dilutions should be used giving 200 or more colonies per plate.*

b. Series of Tests: The method of treatment is best shown by the example given in Table I. Two of the 15 tests made on the sample were discarded. The average of the remaining 13 was then found. The difference between each result and the mean is given in the second column, and the square of the difference in the third column. The square root of the sum of these squares divided by 13 gives the standard deviation.

In finding the expected error, Fig. 1 is entered, using the mean count, 398.4, the corresponding expected error, 20, being multiplied by 10,000, the dilution factor. This expected error, divided by $\sqrt{13}$ gives the expected error of the mean. The Lexian ratio is exceptionally low, showing as close an approach to the assumed conditions as is usually obtained. Values from 4 to 6 are more common for tests on single samples. The results are exceptionally accurate and show what can be hoped for with careful work.

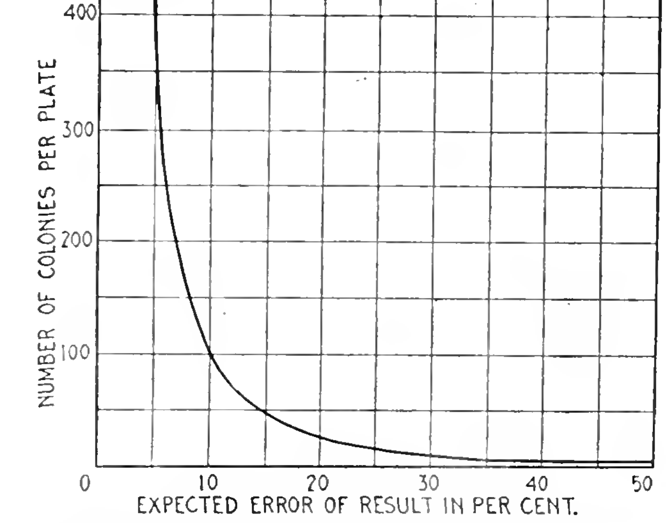

FIG. 2. THE PRECISION OF BACTERIAL COUNTS

TABLE I. TESTS ON A SINGLE SAMPLE OF RAW SEWAGE

Incubation, 24 hours at 37° C. Dilution, 1/100 x 1/100
Controls, 0-0-0. Special care used

	Count	Deviation	Deviation²
1	3,780,000	204,000	41,600,000,000
2	4,340,000	356,000	126,600,000,000
3	3,800,000	184,000	33,900,000,000
4	840,000 (omitted)		....
5	4,280,000	296,000	87,600,000,000
6	3,340,000	644,000	414,000,000,000
7	3,980,000	4,000	16,000,000,000
8	3,300,000	684,000	466,000,000,000
9	4,370,000	386,000	149,000,000,000
10	4,160,000	176,000	31,000,000,000
11	4,060,000	76,000	5,760,000,000
12	3,730,000	254,000	64,500,000,000
13	3,650,000	334,000	111,200,000,000
14	5,000,000	1,016,000	1,030,000,000,000
15	Overgrowths		....
Mean	3,984,000		2,577,160,000,000

$$\text{Standard Deviation } \sqrt{\frac{2,577,160,000}{13}} = \pm 445,000 = \pm 11.2\%$$

$$\text{Maximum Deviation } \begin{cases} = +\ 1,016,000 = +\ 25.5\% \\ = -\ 684,000 = -\ 17.1\% \end{cases}$$

$$\text{Expected Error} = \sqrt{398.4 \times 10,000} = \pm\ 200,000 = \pm\ 5.0\%$$

$$\text{Lexian Ratio} = \frac{445,000}{200,000} = 2.2$$

$$\text{Mean Error} = \frac{445,000}{\sqrt{13}} = \pm\ 123,000 = \pm\ 3.1\%$$

II. *Repeated Samples*—Repeated samples are to be considered the usual routine tests, one or more per day, made in water-works and sewage laboratories. The essential difference, as compared to the single sample, is the variation from sample to sample, in the bacterial content of the liquor being examined, due to river fluctuations, wind currents, seasonal changes, etc. Considerable importance is usually placed upon monthly and even yearly averages of daily tests. These, in themselves, while not to be ignored, should not be given undue weight, unless accompanied by the standard deviation and Lexian ratio, which will give an idea of the variation from ideal conditions. In sanitary work particular interest attaches to exceptionally large values, which calls attention to the individual samples tested. In order that the results of these may be reasonably reliable, the writer recommends that two conditions be observed: (1) Use such quantities in the tests as will give 200 or more colonies per plate, if possible; (2) make from three to 10 tests of each daily sample. Plotting the daily results graphically in the order of their magnitude gives a very clear picture of the type of distribution.

Repeated samples are computed exactly as are repeated tests on single samples, but generally the Lexian ratio will be much larger, from 5 to 15.

THE BACILLI COLI TEST—The presence of the colon bacillus in a water-supply is indicative of pollution, and a consideration of the factors governing its presence will show that the intensity of pollution must be proportional to the density, or number per unit volume of water, of this species present. Unless, therefore, we wish to restrict our classification of waters, according to this test, to polluted, if present, and unpolluted, if absent, it is necessary to have numerical results. The fermentation test used in the determination of coli indicates merely their presence or absence. A certain percentage of positive results gives no direct measure of the degree of pollution, nor does it allow of comparison between different waters, since the causative factors are not necessarily the same. The combination of the percentages of several series of tests, as in the coli index, while creating a false sense of security, through its apparent definiteness, only serves to obscure actual conditions the more. While some method of direct counting would be highly desirable, the best that can be done, in its absence, is to interpret the fermentation test by means of the laws of probability, under certain well defined restrictions, and with a full appreciation of the limits of accuracy involved.

Such a method was described by the writer in a previous article ("Making the B. Coli Test Tell More," Stein, *Engineering News-Record* of May 24, 1917, p. 391) and the theory and application were more fully discussed in a pamphlet privately circulated. For cases of a number of tests made upon a single sample this method gives the very simple formula, $x = -\log_e Q$, where x = the number of coli in the quantity tested, and Q = the proportion of negative tests in the series.

By using 1-cc. quantities x becomes the number of coli per cubic centimeter. The curve for 1-cc. tests is shown in Fig. 3. For other sizes of tests it is necessary to divide by the size of test to obtain the number of coli per cubic centimeter. By use of this curve it becomes a simple matter to find the most probable number of coli for any percentage of positive tests.

The corresponding formula for the expected error becomes rather involved, but the values for 10, 30 and 100 tests are shown graphically in Fig. 4, and the desired values can be picked therefrom. For sizes of tests other than 1-cc., division by the size of test is necessary to obtain results per cubic centimeter.

In Fig. 5, the expected errors have been plotted as percentages. This may be called the precision diagram and is of considerable interest. It brings out:

1. *Ten tests are the least that should be used in determining the percentage of positive tests in a single sample.* Ten tests give an error of from 45% to 50%, which is certainly quite large, but the burden of laboratory work involved in making a large number of tests upon each of a continuous series of routine samples evidently requires some consideration. The error can be reduced in proportion to the square root of the number of tests made. Thus, for 100 tests the error for 10 tests should be divided by $\sqrt{10}$, for 200 by $\sqrt{20}$, etc. To obtain results within $\pm$ 10% requires 200 tests, $\pm$ 5%, 800 tests! It is unfortunate that this test, of much greater sanitary significance than the bacterial count, should be so inexact.

2. *For reliable results, the percentage of positive tests should lie roughly between 35 and 85.* Closer limits can be obtained by inspection of the individual precision curves. Below 35% the error increases very rapidly and above 85 the curves abruptly change their slope and pass into a region of indetermination.

3. *Of three dilutions in the usual geometrical progression of 10, 1.0, 0.1, only one can be in the range of reliable results.* This follows directly from (2) and has been checked by the examination of a large number of actual results. A coli value by the method given above, based upon the combination of three dilutions, is less exact than would be obtained by selecting the one of the three which lies within the range of reliable results. This point applies with even greater force to the coli index, since therein the lower of the three values is given 10 times the weight of the middle (and usually the most accurate) one. Of course, dilutions closer together might be used, but then there is the possibility of all of them being outside of the limits, so that it is better to use the multiples of 10, and select that set which comes within the range.

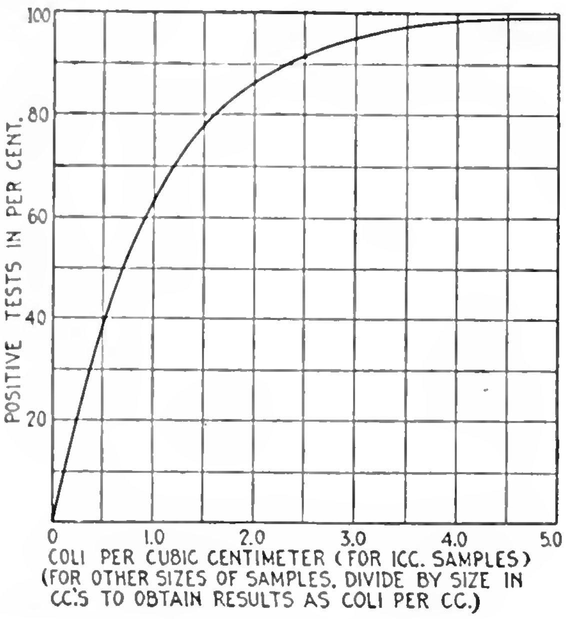

FIG. 3

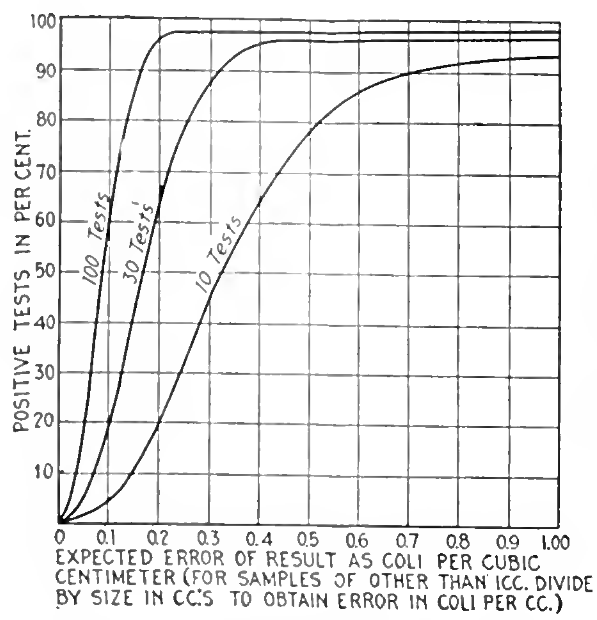

FIG. 4

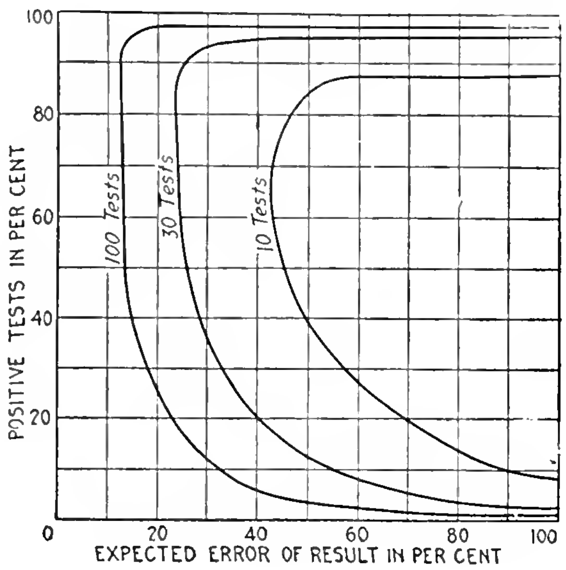

FIG. 5

FIG. 3. MOST PROBABLE NUMBER OF COLI CORRESPONDING TO ANY PERCENTAGE OF POSITIVE FERMENTATION TESTS. FIG. 4. THE EXPECTED ERROR IN COLI RESULTS. FIG. 5. THE PRECISION OF COLI RESULTS

THE BACILLI COLI TEST—REPEATED SAMPLES—If there is so much uncertainty in the results of fermentation tests on a single sample, how must matters stand in the case of repeated samples, such as the daily tests (usually one each of several dilutions) made at filtration plants? The density of coli in almost every water varies from day to day, so that the daily results are in fact only single tests taken haphazard from a number of series, each of which, if developed, would yield a different percentage of positive tests. Therefore, unless it is definitely known that the coli content of a water is practically constant from day to day, any percentage or other computation based on a series of single daily tests is of little value, and unless such a constancy has been experimentally verified it is necessary to make a series of tests, not less than 10, each day, if it is desired to avoid the danger of being entirely misled by the results.

TABLE II. RESULTS OF DAILY SERIES OF COLI TESTS FOR 10 DAYS
(1-cc. samples)

Column	1	2	3	4	5	6	7	8	9	10	P	Coli
Monday	+	—	+	—	+	—	—	+	+	+	0.6	0.9
Tuesday....	—	+	—	+	—	+	—	+	—	—	0.4	0.5
Wednesday	—	—	—	+	+	+	+	+	+	+	0.7	1.2
Thursday	—	+	—	—	—	+	—	—	—	+	0.3	0.35
Friday......	+	+	+	+	+	+	+	+	+	—	0.9	2.3
Saturday...	—	—	—	—	—	+	—	—	—	—	0.1	0.1
Sunday....	—	+	—	—	—	+	—	—	—	—	0.2	0.2
Monday.....	—	—	—	+	+	+	+	—	+	+	0.5	0.7
Tuesday....	+	+	+	+	—	+	+	+	+	—	0.8	1.6
Wednesday.	+	+	—	+	+	—	+	—	+	+	0.7	1.2
Mean												0.91

This may be shown by Table II, which represents the results of 10 tests on a single sample each day for 10 days. The mean number of coli was 0.91 per cubic centimeter. If only one test had been made each day, the results obtained might have been as in column 3, which gives 0.3 positive, or 0.35 coli per cubic centimeter, or they might have been as in column 6, —0.8 positive or 1.6 coli per cubic centimeter or any one of many other combinations.

TABLE III. THE STATISTICAL COMPILATION OF BACILLI COLI TESTS
1-cc. Samples

Date	P	Coli	Deviation	Deviation
1/11	0.6	0.9	0.0	0.00
1/12	0.4	0.5	0.4	0.16
1/13	0.7	1.2	0.3	0.09
1/14	0.3	0.35	0.00	0.30
1/15	0.9	2.3	1.4	1.96
1/16	0.1	0.1	0.8	0.64
1/17	0.2	0.2	0.7	0.49
1/18	0.5	0.7	0.2	0.04
1/19	0.8	1.6	0.7	0.49
1/20	0.7	1.2	0.3	0.09
Mean........................		0.9		4.26

Standard Deviation $= \sqrt{\frac{4.26}{10}} = \pm 0.65 = \pm 72\%$.

Expected Error = Value P corresponding to 0.9, from Fig. 3 = 0.6; from Fig. 4, the expected error for $P = 0.6$ and 10 tests is ± 0.38.
Lexian Ratio = 0.65/0.38 = 1.71.
Mean Error $= 0.65/\sqrt{10} = \pm 0.21 = \pm 32\%$. This value is included merely to show the method of computation. Where results are very irregular its use is not warranted.

Assuming that 10 or more tests are made per day, the summarizing of results for 10 days, 30 days or for a longer period is very similar to the method used for the bacterial count. Using the data in Table I, the procedure is shown in Table III, and calls for little comment. If 0.1-cc. samples had been used, it would have been necessary to multiply the values under "Coli" by 10; whereas if 10-cc. quantities had been used, the same values would have been divided by 10, as previously explained.

New Projection in Map of United States

Using a new system of projection, known as the Lambert conformal conic projection, the United States Coast and Geodetic Survey has just issued an outline map of the United States, scale 1: 5,000,000 and 25 x 39 in. in size. By this system of projection the average scale error is much reduced from that in other systems commonly used. For instance, between latitudes 30½° and 49°, the maximum scale error is only ½%. The Lambert projection is well adapted to large areas of predominating east and west dimensions as the United States, where the distance across from east to west is 1⅗ times that of the distance north and south. The strength of the polyconic projection, on the other hand, is along its central meridian. Special features of the Lambert projection that are not found in the polyconic are claimed as follows: (1) The Lambert projection is conformal; that is, all angles between intersecting lines or curves are preserved; and, for any given point (or restricted locality), the ratio of the length of a linear element on the earth's surface to the length of the corresponding map element is constant for all azimuths or directions in which the element may be taken; (2) the meridians are straight lines and the parallels are concentric circles; (3) it has two axes of strength instead of one, the standard parallels of the map of the United States being latitudes 33° and 45°, and upon these parallels the scale is absolutely true.

Water-Meter Practice and Testing at Buffalo, New York

Special Testing Bench for Large Meters, Cubic-Foot Pail for Skeptical Householders, and Non-Freeze Settings

By Carl L. Lund
Hydraulic Engineer in Charge of Buffalo Meter Shop

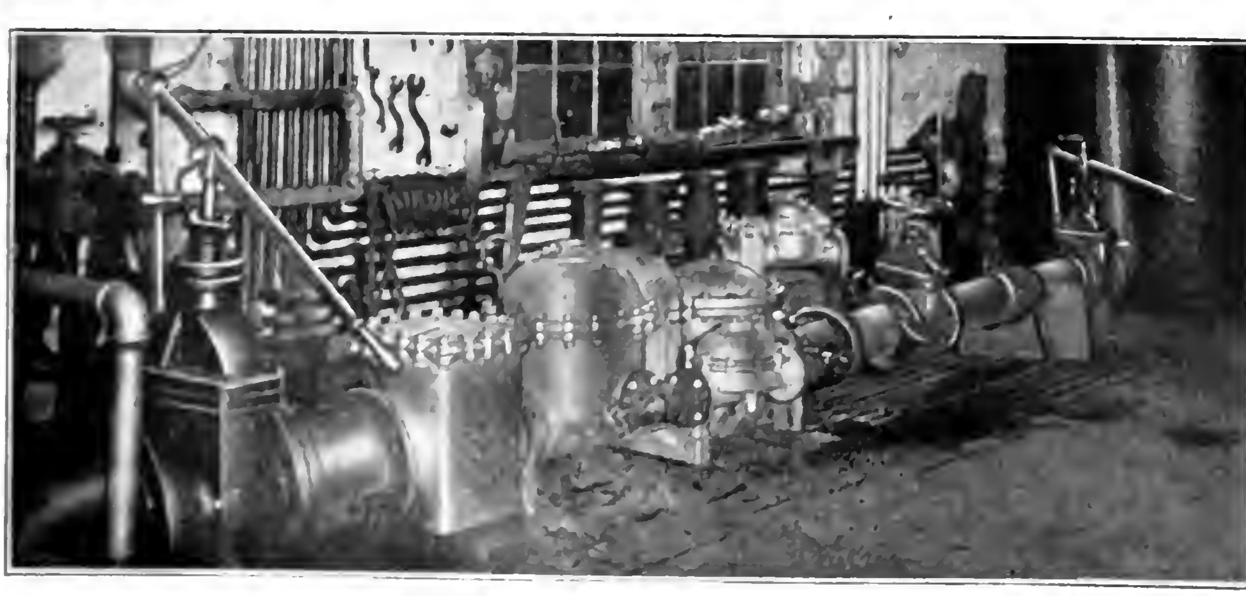
ALTHOUGH 7% only of the 75,325 water services in Buffalo, N. Y., are metered, 46% of the revenue is obtained for metered water. The meter division is, therefore, considered one of the most important branches of the water department. To show how it functions from initial installation to final replacement is the present object.

The city furnishes and installs all water meters, making a nominal charge for labor and fittings. All meters are maintained without expense to the consumer unless the meter should disappear; then he pays for it. If the meter should be ruined by hot water or be frozen, the consumer pays for the damage. A charge is made also for repairing or changing meters after the working hours of the water-department employees. It happens frequently, especially in the large office buildings or offices of corporations, that when we ask, "What is a convenient time to make the repairs?" the reply is, "After we have shut down for the day." In 90% of these cases, when the consumer is informed that he will have to pay for the overtime of the men he finds time to permit the making of the repairs in working hours. Furthermore, if this were not done it would be an inducement to the employees to put off the repairs for the overtime.

Meters are installed in the buildings as far as possible, but where the connections are such that this cannot be done the $\frac{5}{8}$-in. and $\frac{3}{4}$-in. meters are placed near the curb in an 18-in. tile with an iron cover and an 11-in. opening. The larger meters are installed in concrete vaults with a flat-iron frame and cover made by a local foundry. The small meters of the outside installation are brought up to within 15 in. of the surface, and the tile is filled to within 6 in. of the meter. During the severe winter of 1917-18 only half a dozen of the outside meters were frozen, and in each case the service froze in the building first. In the same winter there were over 100 meters frozen inside buildings. A yoke with a stop-cock at each end is used for the small outside installations, as it saves time in changing meters. In the installation of large meters the department requires a valve on both sides of the meter and a 2-in. tee between the outlet side of the meter and the valve. This is for use in making tests of the meter at frequent intervals. A siamese or battery connection is required so as to place two meters instead of one, as with this installation there is no need of the consumer being entirely without water while repairs are being made.

At the present time five meter readers do nothing but read the meters. The readings are taken monthly, and if the reader thinks there is something wrong, or if the meter is stopped, he has an order issued and the meter is sent to the meter shop for investigation. This order is given to the plumber who has charge of the district, and unless he is positive that there is nothing wrong he is supposed to change the meter. We have found that time is saved by taking the meter to the shop, as the disk may be broken, the spindle worn, the train-gear gone, the pinions stripped, or parts of the dial loose. Should the meter reader find a large discrepancy in the previous consumption, he has an order made to investigate for leaks, and the bill is not sent to the consumer until the investigation is made and we are positive that the reading is correct. No complaints are received of under-registering of the meters, but as soon as a bill rendered is larger than usual we are notified that the meter is wrong. For complaints of small meters we make a test on the property by using a 7½-gal. copper pail. For the large meters we use a 2-in. meter and test the two meters in tandem, through the 2-in. test tee. We find the cubic-foot pail more satisfactory to the water-rate payers, as they are always skeptical of a meter.

It is the intention to change meters every two years or oftener, according to consumption. The Lake Erie water is turbid at times, filling the meter with silt. This is bad for the rotary meter, which will under-register 12% in two years. According to the Buffalo rules, meters must register within 2%, plus or minus, and must register water through a $\frac{1}{8}$-in. opening before it can be reset. We find that it is impossible to get the meter to run on a smaller stream without spending a greater amount of time than is commensurate with the revenue we receive at 4c. per 1000 gal. At 40-lb. pressure (which is higher than the average) we find that a meter repaired in the shop and tested perfectly on all streams, including $\frac{1}{8}$-in., will, after a few days, be brought back to the shop, and the best we can get this meter to do is a $\frac{1}{4}$-in. stream.



TESTING OUTFIT FOR LARGE METERS HAS QUICK-OPENING INLET AND OUTLET VALVES

The meter-repair division is located in a one-and-a-half story brick building at Lake View Ave. and Jersey St., in conjunction with the general repair division. It is also near the Col. Francis G. Ward pumping station. The meter shop is 200 ft. x 50 ft., with a stock room 20 ft. x 40 ft. in the center and adjacent to the meter repairer's bench. In the stock room are 1300 compartments for fittings and repair parts. From a 48-in. main in Lake

View Ave. there is a 10-in. connection for the shop. A 2-in. line supplies the testing machine for small meters up to 2-in. A special testing bench, designed and constructed by the writer, is used for the larger meters. The layout is as follows: A 10-in. supply comes into the building and up to a 10-in. flanged quick-opening valve (there is a 10-in. air chamber just inside the building wall); then a 10 x 8-in. flanged reducer, followed by an 8 x 6-in. flanged reducer, then a reducer to fit any size of meter, and, finally, space for a meter. The line is then increased to a 6-in. screw gate valve, and a piece of 6-in. pipe is followed by a 6-in. quick-opening valve. On this piece of 6-in. pipe there is a special flanged joint for inserting bronze disks with openings of various sizes, from 4 to ⅛ in. The discharge is through a 7-ft. riser over the top of a 60-in. cast-iron pipe set on end on a concrete foundation, with a 6-in. outlet to the sewer. The outlet is controlled by a 6-in. quick-opening valve. This is a volume tank, and the amount of water that is registered shows through glass gages in three 4-ft. sections, with a wood board painted to show cubic feet. The bottom of the 60-in. pipe is 5 ft. below floor level, with the zero of the gage at floor level, so zero is always at water level. A third testing machine is used by the meter repairers to tell how small a stream the meter will register.

The present force and the salaries of the meter division are as follows: One general foreman, $1500 per year; one clerk, $1200 per year; two plumbers, $110 per month; three meter repairers (outside work), $4 per day; two meter repairers (shop work), $3.75 per day; one repairer and tester (large meters), $3.75 per day; four plumbers' helpers, $3.25 per day; one plumber's helper, $3 per day; one meter tester, $3 per day, and one laborer, $3 per day. The Bureau of Water is under the Department of Public Works, of which Arthur W. Kreinheder is commissioner and George C. Andrews is water commissioner. The writer is hydraulic engineer in charge of the meter shop.

Design and Tests of Highly Efficient Air-Lift Installation at Fort Bliss, Texas

Novel Foot Piece, Well Proportioned Eduction Pipe, and Special Head Tanks Give 51.9 Per Cent. Air-Lift Efficiency—Overall Efficiency 28.6 Per Cent.—Test Figures and Operating Costs Given

By Captain J. F. Brown
Quartermaster Corps., Engineering Branch, Construction Division of the Army, Kansas City, Mo.

In the light of experience, extending over several decades, in the use of compressed air for lifting water from wells, engineers are inclined to receive, not without a degree of skepticism, reports of actual installations which are operating at high efficiency. Careful analysis of conditions to be met and thorough study of plants of a similar character, on the part of the designing engineer, have, however, made possible the design and installation of such a plant at Fort Bliss, Texas, tests of which show operating efficiencies never before attained—51.9% as the average of the better of two sets of air-lift tests and 28.66% as the corresponding overall or wire-to-water efficiency. The foot piece, consisting of a double conical bronze casting (inverted cone at lower end), set within and at the foot of the eduction pipe, is the special feature of design. Particular attention was also given to the proportions of the eduction pipe and to the head tanks at the top of each eduction column. Small water-storage reservoirs, with sand-settling compartments and measuring weirs, are provided.

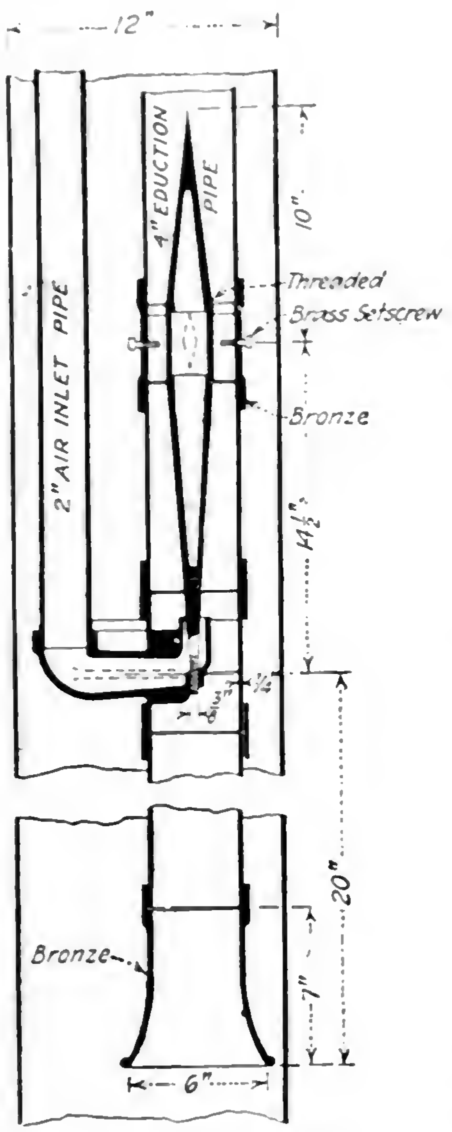
Water for all needs of the permanent military establishment, as well as for several bodies of troops encamped temporarily on the Fort Bliss military reservation, is supplied from four bored wells, each 600 ft. deep, and is pumped from these wells into surface reservoirs by means of compressed air. From the surface reservoirs the water is pumped directly into the distributing mains by means of centrifugal pumps. According to information obtained during the drilling of the wells, eight distinct water-bearing strata are penetrated, the first, or uppermost, being about 220 ft. below the surface, at which depth is the normal water plane.

These wells, two of which are 10 and the other two 12 in. in diameter, are cased to the full depth with standard threaded steel casing. From the normal water plane to the bottom the casings are perforated with ½ x 10-in. vertical slots, the area of opening being 10 sq.in. per foot of casing. In the 10-in. wells drilled in 1913 the slots were cut by means of air-operated hammers, while in the larger wells, drilled in 1917, they were cut by means of an oxyacetylene torch. The latter method proved to be much more rapid and less costly than the former.

Air for operating the four wells is supplied by four duplex, two-stage compressors, two of which are equipped with high- and low-pressure cylinders 7½ and 14 in. in diameter, respectively, the other two being equipped with cylinders of 7- and 12-in. diameters, respectively, and all having a 12-in. stroke. At the normal speed of 190 r.p.m., the two larger compressors deliver 320 cu.ft. of free air per minute each, and the smaller ones 260 cu.ft. each, when operating against a terminal gage pressure of 150 lb. The cylinders are equipped with Corliss-type intake and direct-lift-type discharge valves, and are water-jacketed. Each compressor is provided with a brass-tube intercooler having a cooling surface of 50-sq.ft. area.

All of the compressors discharge into a 6-in. header, at each end of which is an air receiver 3½ ft. in diameter and 10 ft. long. From each receiver compressed air is distributed to two wells, the air-supply line to each well being 3 in. in diameter. At the well head the air line is reduced to 2 in. and extends into the well between the casing and the eduction column to a depth of approximately 540 ft., at which point it connects into a specially designed cast bronze foot piece.

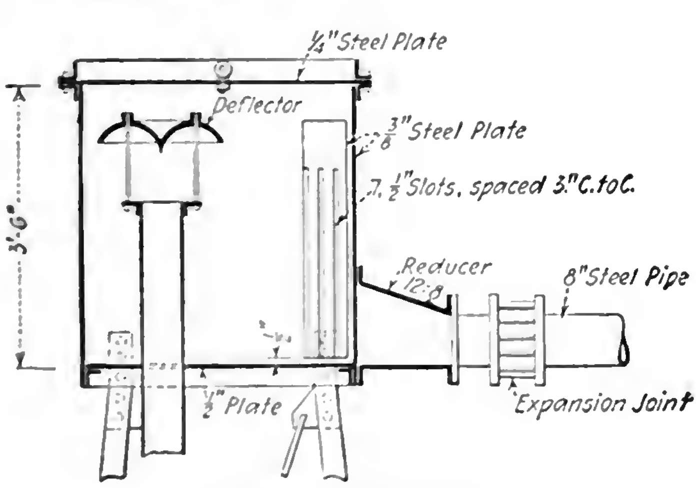
The function of the foot piece, shown (see next page) is to facilitate the thorough mixing of the current of air and the rising column of water. This highly important feature of the installation differs radically from the well-known commercial types of foot pieces. It consists



AIR LIFT FOOTPIECE

essentially of a double conical bronze casting supported concentrically within the eduction column, the apex of the lower cone extending just into the compressed air inlet. From this point the velocity of the rising column of water is increased, due to the decreased area of the section, until the throat section at the base of the cone is reached, at which point the velocities of the two currents are very nearly equal. In this portion of the foot piece there occurs the thorough mixing of air and water, the two fluids passing through the throat section in a thin sheet or film. The upper cone serves to provide a steadily increasing section, thus preventing a separation of air and water which would be caused by the shock due to a suddenly increasing section. The eduction column was designed of such proportions that the maximum velocity of the rising column of water and air should not exceed 25 ft. per second at any point when the well was delivering at the normal rate, and increases in diameter from 4 in. at the foot piece to 7 in. at the top.

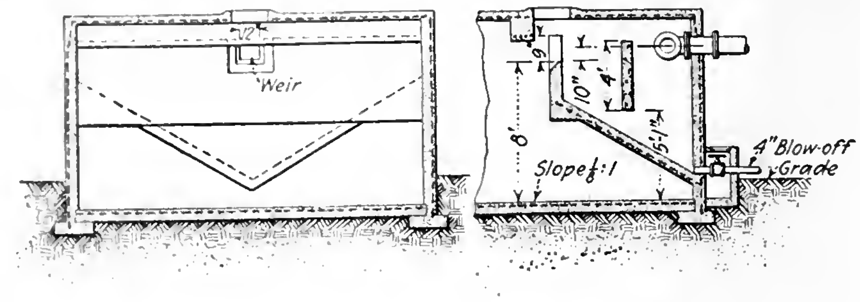
At the upper end of each eduction column is a cylindrical steel head tank (see below), 3½ ft. in diameter and 3½ ft. in depth, within which is supported, just above



AIR LIFT HEAD TANK

the end of the pipe, an umbrella-shaped cast-iron deflecting vane, whose function is to break the force of the rising column of water and air. The head tanks are closed at their tops by means of steel plates, bolted on over rubber gaskets to prevent the escape of air. From the head tanks water and air flow through 8-in. galvanized-steel pipe lines supported on angle-iron frames and concrete piers, to two covered rectangular reinforced-concrete reservoirs of 46,000 gal. capacity each. Each reservoir contains a small settling chamber, in which the sand coming from the wells subsides, and a rectangular weir for measuring the rate of discharge from the wells. (See illustration below.)

Horizontal, double-suction, single-stage, volute-type, centrifugal pumps are used for pumping the water



RESERVOIR WITH SAND-SETTLING COMPARTMENT AND WEIR

from the surface reservoirs into the distributing mains. There are four of these pumps, each rated to discharge 600 gal. per minute against a head of 135 ft. at a speed of 1760 r.p.m., although two of them have a discharging rate of about 1000 gal. per minute when operating against that head.

All of the compressors and centrifugal pumps are driven by constant-speed, induction-type motors. The motors for the two larger compressors are rated at 75 hp. each and operate at a speed of 580 r.p.m., while those for the two smaller compressors are rated at 61 hp. each and operate at a constant speed of 1150 r.p.m. Each centrifugal pump is direct-connected by means of a flexible coupling to a 40-hp. motor, which operates at a constant speed of 1760 r.p.m. Electric current for operating these motors is bought from the El Paso Electric Railway Company.

Upon completion of the original installation, consisting of the two larger compressors and two centrifugal pumps, a series of tests, or trial runs, was made to ascertain the efficiency of operation of the plant, particularly of that portion of the plant used for lifting water from the wells. During the past year the capacity of the plant has been practically doubled by the installation of additional compressors and pumps, and upon completion of this work a second and more comprehensive series of tests was made. No effort was made to ascertain the mechanical efficiency of the individual units, such as motors, pumps, compressors, etc., since each of these had been tested at the various factories under the supervision of Government engineers, and it is understood that they met fully the specifications and the manufacturers' guarantees.

In preparing the plans and specifications for the plant consideration was given to the desirability of making frequent operating tests of the different portions of the plant, with the result that it was determined to provide in the permanent installation such gages and meters as would be necessary in obtaining the desired data.

The series of tests, or trial runs, on the air-lift installations is divided into two sets. In the first set, the power input to the compressor motors was obtained from readings of the recording dials of the watt-hour meters on the switchboard; the speeds of the motors and compressors by means of revolution and stroke counters; the rate of delivery of compressed air to the wells from readings of the scale of the manometer of the air meter; the air pressure from gages on the air receivers and at each well head; and the rate of delivery of water from the wells from the weir gage. In the second set of tests the power input to the com-

pressor motors was obtained by counting the number of revolutions of the rotating disks in the recording watt-hour meters, the rate of delivery of water from the wells from actual volumetric measurements by means of the surface reservoirs, and all other data as in the first set. The methods of obtaining the power input to the motors and the rate of delivery from the wells, as used in the second tests, are thought to be much more accurate than those used in previous tests, because unit rates are derived from totals for a given period of time rather than from direct observations.

The series of tests on the centrifugal pumping units is divided into three sets. In the first of these the power input to the motors driving the centrifugal pumps was obtained from readings of the dials of the recording watt-hour meters on the switchboard; the speed on the unit by means of a revolution counter; the rate of delivery of water and the total volume delivered during the test from the indicating and registering dials of the manometer of the venturi meter, and the head against which the pump was operating from the recording altitude gage. In the second set of tests, the power input to the motors was obtained as above described, and the total volume of water pumped during each test was measured volumetrically. In the third set, the power input to the motors was obtained by counting the revolutions of the rotating disks of the watt-hour meters, and all other required data were obtained as in the first set.

Results calculated from data obtained during the tests described are given in the accompanying table. The average efficiency of the air-lift for the first set of tests was 48.1 and for the second tests 51.9%. The average overall efficiency (wire to water) for the air-lift end of the plant for the first set of tests was 26.4% for the first and 28.66% for the second set of tests.

For the centrifugal pumping units the average overall efficiency (wire to water) for the first set is 43.6%, for the second 49.27% and for the third 55.93%. The results obtained in the first and second sets show overall efficiencies of the pumping units on the basis of useful work done. The power applied to the motors is consumed in actually pumping water against the pressure head in the distributing system. In the third set of tests, in which the pumps were throttled on the discharge side to give the desired rate of discharge, the statement of efficiencies is the relation between the power applied to the motors and the actual work done by the pump in forcing water through the partially closed gate valve in the discharge line and against the pressure head in the distributing system. The results in this set are interesting, therefore, only as indicating the actual overall efficiencies of the units.

The average power requirement for lifting water from the wells to the surface reservoirs is 2.77 kw.-hr. per 1000 gal. of water, and that for pumping the water from the surface reservoirs into the distributing system is 0.798 kw.-hr. per 1000 gal., under average working conditions of pressure and rate of delivery. At an average cost of 1.5c. per kilowatt-hour, the actual cost for power alone for delivering 1000 gal. of water into the distributing system is 5.34c. The cost for the pumping station crew, consisting of a chief engineer and one assistant engineer and one laborer on each of three daily shifts, and also including the cost of incidental supplies, such as lubricating oil and waste, is 1.66c. per 1000 gal., making the total actual cost 7c. per 1000 gal. The actual outlay of funds for this plant is $101,767, the original installation, including the two 10-in. wells, having cost $42,700 and the addition to the plant, including the two 12-in. wells, having cost $64,067. Interest at the rate of 4% upon the cost of the installation, and depreciation of equipment at the rate of 5%, are provided for by adding 2.63c. per 1000 gal., making the total cost for supplying water 9.63c. per 1000 gal., on the basis of a plant capacity of 1,000,000 gal. per day. Prior to the completion of the plant, water purchased from the El Paso Water Co. to supply the needs of Fort Bliss cost 20c. per 1000 gal. At an average daily demand of 1,000,000 gal., the annual saving to the Government effected by the operation of this plant is $37,850. If the plant capacity is taken as 1,500,000 gal. per day, which is its normal working capacity, providing for the shutting down of one compressor and one well, the total cost of supplying water is 8.21c. per 1000 gal., and the annual saving to the Government is $64,550. Taking the plant capacity as 2,000,000 gal. per day, which is the ultimate capacity of the present installation, the total cost per 1000 gal. is 6.74c., and the annual saving is $96,798

The original investigations and studies of the problem of providing an adequate water-supply for Fort Bliss, and all original designing in connection with the preparation of the plans for the project, were carried out during the years 1915-16 by Leonard S. Doten, who was at that time sanitary and hydraulic engineer in the

construction and repair division, Office of the Quartermaster General of the Army. The preparation of the plans for the addition to the plant in 1918 was also accomplished under his direction as advisory engineer on sanitation, Construction Division of the Army. The contractor for the original equipment installation was the Perry Electric Co., of Brooklyn, N. Y., and the general contractor for the addition to the plant was the Jennings Construction & Engineering Co., of El Paso, Tex., the drilling of the wells having been done by local contractors. The writer, at that time civil engineer for the construction and repair division, Office of the Quartermaster General of the Army, superintended the original installation and had charge of the preparation of plans for the addition to the plant, and conducted the tests described herein.

Centrifugal Pumps at the Chicago Water-Works Plants

Electric Power More Satisfactory Than Steam—Two 40,000,000-Gallon Pumps With 1100-Horsepower Motors Being Installed

EXTENSIVE use of centrifugal pumps for the Chicago water-works is due partly to the fact that the small floor area required enabled them to be placed in existing pumping stations which had no room for additional steam equipment, and partly to a movement for electrical operation of the pumping plants together with the low cost of an electrically operated centrifugal plant as compared with that of a steam-operated reciprocating plant. This movement has been backed by the Sanitary District of Chicago, in order to increase the city's consumption of current generated at the hydro-electric plant on the Drainage Canal. There are now 16 centrifugal pumps, with rated capacities ranging from 5,000,000 to 40,000,000 gal. daily, and six of these are electrically driven.

Steam-turbine centrifugal pumping units are reported to have given considerable trouble in operation, so that there is reluctance to install more machinery of this kind, at least where permanent service is required. The difficulties consist mainly in minor failures of turbine parts which necessitate shutting down the unit, but it has not been determined whether these are caused by unfamiliarity on the part of the operators or by defects in the machinery, or both combined. With motor-driven units there has not been much trouble. However, a flooding of the 22nd St station, which caused the putting of all electrical units out of service for a considerable time, has indicated certain difficulties against which provision must be made.

The first centrifugal pump installation was made in 1910 at the 22nd St. pumping station. Additional capacity was needed to serve the stockyards district, but there was neither floor space nor boiler capacity for new steam units. The city engineer decided, therefore, to adopt motor-driven centrifugal pumps, which could be placed in the existing pump pit. The two pumps are each of 25,000,000-gal. capacity against 130-ft. head, directly connected to induction-synchronous motors having a rated capacity of 1000 brake-horsepower, 800 kva. The speed of pumps and motors is 514 r.p.m. This type of motor has the advantage of greater starting torque than a synchronous motor, while retaining the simple starting method of an induction motor. Current was furnished by the Sanitary District of Chicago, and was stepped down from 12,000 to 440 volts. These units have been in continuous service since 1911, pumping for much of the time at the rate of 20,000,000 to 30,000,000 gal. daily, or about 25% above the rated capacity. Their satisfactory service led to further use of the system.

Two steam turbine driven, direct-connected pumps of 20,000,000-gal. capacity, operating at 1500 r.p.m. were installed for temporary service at the Lake View pumping station in 1912. Four similar units of 25,000,000-gal. capacity, operating at 1550 r.p.m. were installed in 1913, one each for reserve at the 14th St., Harrison St., Central Park Ave. and Springfield Ave. stations. In 1914, two similar units for booster service were installed at the Roseland station, being of 5,000,000 gal. capacity and operating at 2750 revolutions per minute.

New equipment for the 68th St. station was needed at about this time, but as there was a probability of this station being abandoned in favor of a new location, it was not considered advisable to incur the heavy expense of new reciprocating pumps. To meet these conditions, the two 20,000,000-gal. turbine-driven pumps at the Lake View station were moved to 68th St. in 1914. Two 30,000,000-gal. units were installed at the latter station in 1916, but in this case reduction gears of the herring-bone type were used, the speeds being 3740 r.p.m. for the turbines and 720 r.p.m. for the pumps. It is stated that these units have given more trouble than any of the others, and new gears are now being placed. This station, with its four steam-driven centrifugal pumps, is still in service.

Motor-driven units have been adopted for all other installations, following the general type of the second plant at 22nd St. At the Jefferson Park station a 3,000,000-gal booster pump was installed in 1913, and two of 2,000,000 gal. in 1915. All had slip-ring induction motors, with speeds of 1140 r.p.m. for the smaller and 865 r.p.m. for the larger machines. These three booster machines were dismantled in 1918. Two 25,000,000-gal. pumps directly connected to 875-hp. induction motors, operating at 440 volts and with a speed of 720 r.p.m. were installed in the 22nd St. station in 1918, replacing some of the old steam pumps and supplementing the original electrical installation of 1911.

The largest centrifugal pumping units (which are not yet in service) are two 40,000,000-gal. machines, having a maximum rating of 50,000,000 gal., to replace two old steam pumps of 25,000,000-gal. combined capacity at the Chicago Ave. station, where there still remain three modern steam reciprocating pumps of 25,000,000 gal. each. The new centrifugal pumps will be directly connected to slip-ring induction motors of 1100 hp., operating at 2300 volts and with a speed of 720 r.p.m. An overall efficiency of 72.3% for pump and motor is required for this plant, which, it is expected, will be put in service in 1919.

All these installations of centrifugal pumps for main and supplementary units have been planned by and made under the direction of John Ericson, city engineer
made under the direction of John Ericson, city engineer.

More Metering for Salt Lake City

Under an amendment to a city ordinance of Salt Lake City, Utah, dating from the beginning of 1919, all new services are to be metered. At present about 25% of the services are fitted with meters. A water-waste survey is contemplated but has not been undertaken.

Municipal Freight-Handling Dock and Cranes at St. Paul

City Now Prepared To Convey Freight From the Mississippi River to Storage Yards, Trucks or Railroad Cars

ST. PAUL, Minn., has just completed a municipal river freight-handling terminal on the Mississippi at a cost of $71,800, and the city is now equipped to transfer river and land freight, if river haulage becomes popular. The terminal comprises main-line railroad tracks on a timber trestle paralleling the river, an adjacent storage yard, a large tower crane mainly to handle coal, and a locomotive crane for smaller loads.

The trestle is 800 ft. long and has two standard-gage tracks connected to the main-line railways. Straddling

CRANE WILL HANDLE RIVER FREIGHT AT ST. PAUL

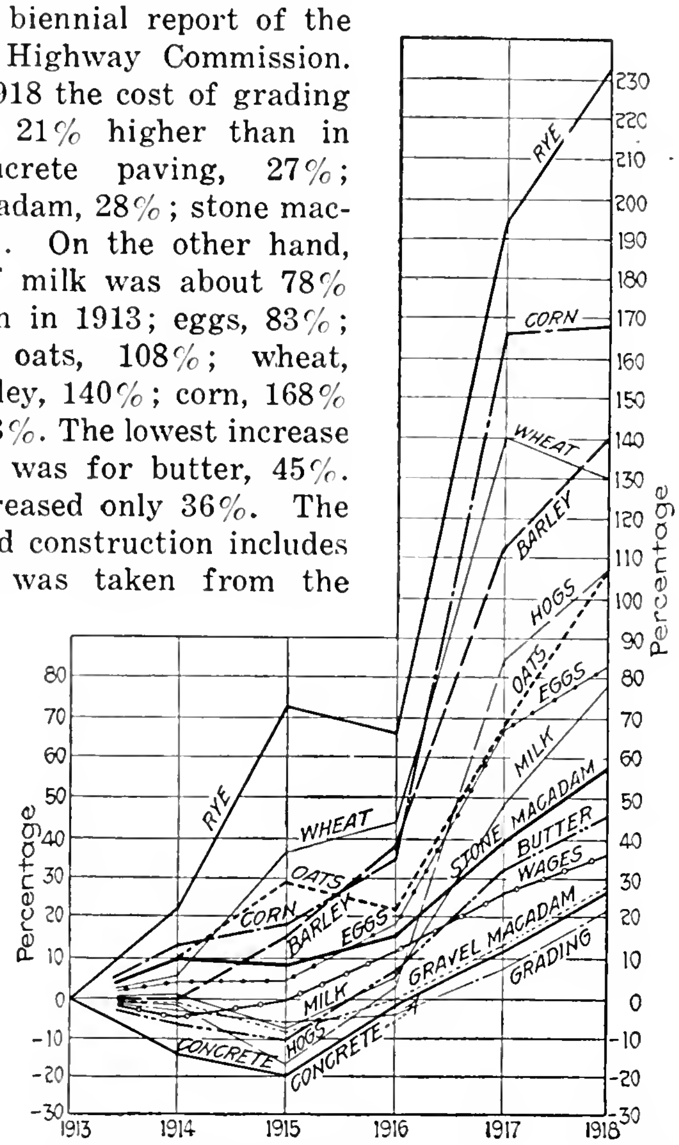
the tracks is the tower shown in the view, equipped with a 2-yd. clamshell bucket traveling on a boom which extends 70 ft. over the river and 85 ft. over the land. This tower is to be used exclusively for handling coal, sand, gravel, package freight, etc. The tower may load directly onto railway cars on the double tracks, to automobile trucks on the marginal way or dump on the storage platfrom. Parallel with the trestle the ground has been leveled off and filled in to provide storage for a width of 100 ft. Here 18,000 cu.yd. of earth fill was made, material being delivered free of charge from building excavations and other sources. The only expense connected with it is that of spreading and leveling.

The locomotive crane, which runs on the trestle tracks, has a 1½-yd. clamshell and a maximum working radius of 50 ft. The mean height of the river is only 10 ft. below the rail on the trestle, although in the view herewith the distance looks much greater.

The work was planned and built under the supervision of O. Claussen, chief engineer, and M. S. Grytbak, bridge engineer, of the city.

Comparatively Small Increase in Cost of Wisconsin Road Building

RELATIVELY low increase in cost of roads in Wisconsin during the war period, 1914-18, as compared with the increase in cost of farm produce, is shown by the accompanying diagram, which is taken from the fourth biennial report of the Wisconsin Highway Commission. Thus, in 1918 the cost of grading was about 21% higher than in 1913; concrete paving, 27%; gravel macadam, 28%; stone macadam, 58%. On the other hand, the cost of milk was about 78% higher than in 1913; eggs, 83%; hogs and oats, 108%; wheat, 130%; barley, 140%; corn, 168% and rye 233%. The lowest increase in produce was for butter, 45%. Wages increased only 36%. The cost of road construction includes labor and was taken from the



RELATION BETWEEN INCREASE IN COST OF WISCONSIN ROADS AND FARM PRODUCE

records of the commission. This chart shows that the farmer can build more road with a measure of produce than before the war.

100-Mile Motor-Truck Express Route

A 100-mile motor-truck express route is reported in operation between Portland and Salem, Ore., the round trip being 110 miles. Two 3½-ton trucks and one 2-ton truck are in use, the larger trucks making a round trip every day, while the two-ton truck is used on rush days and in picking up express packages in Portland. The freight rates range from 30 to 40c. per hundredweight, the trucks picking up and delivering all along the route. The line has had so much business that five tons have been carried every trip. Greater speed is expected when 20 miles of rather rough earth roads are improved. The express consists of taking milk, butter, eggs, veal, poultry, hogs, and vegetables to market, and merchandise on the return trip. E. B. Scott, whose father, Capt. Hugh B. Scott, ran the first light-draft steamer between Portland and Salem on the Willamette River, is behind the undertaking.

Study of Revenue From Sale of Water to Metered Domestic Consumer

New England Water-Works Association Form Based on Service and Output Charge Alone Rational and Equitable — Basing Revenue Estimates on Unregistered Water Leads to Error

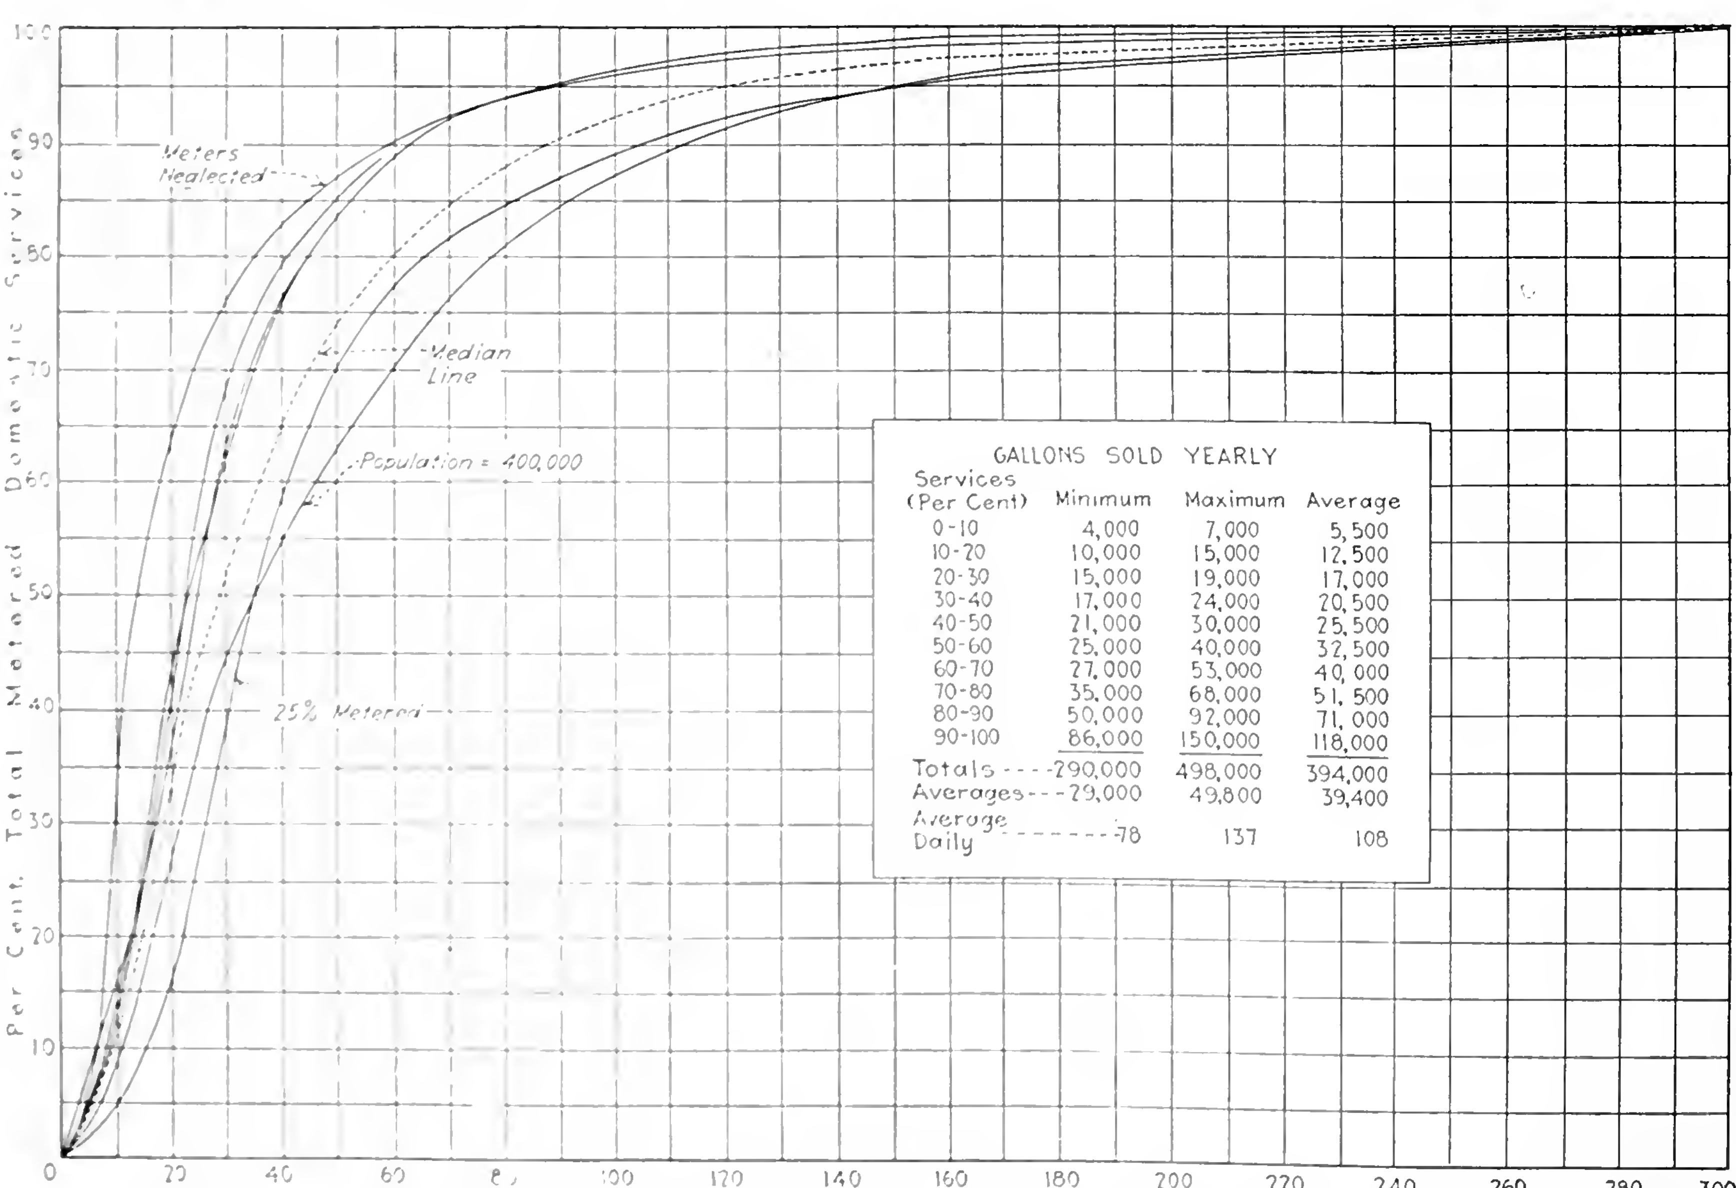
By Philip Burgess

Engineer, Columbus, Ohio, Before the Indiana Sanitary and Water-Supply Association

Control of water rates charged, especially by private companies, is now largely in the hands of state commissions. It is the usual procedure, in adjusting water rates before the commissions, to determine, first, the cost of service, based in part on the reasonable return on the fair present value of the properties and in part on the operating and maintenance cost of the plant; and when the total cost of service is thus determined the schedule of rates is established so that the property will earn an amount at least equal to the total cost of the service rendered. It has been the writer's experience that during such proceedings it is customary to spend much time and effort in determining the value of the property and the cost of service but that little attention is given to the form of the schedule and the individual rates properly chargeable for the service. For this reason it is generally found that, after all the effort, the schedule of rates finally set up does not earn the amount which it properly should earn. This is particularly true when the schedule is changed from flat rates to metered service rates, and is attributable principally to lack of information relative to the amount and distribution of the water sold.

It is the writer's opinion that the determination of a schedule of fair water rates chargeable for metered service requires the setting up of a reasonable service charge, payable whether or not any water is delivered, and, in addition, a reasonable output charge for water actually consumed or sold by the meter. The most interesting and instructive discussions of the service charge are found in the reports of the committee on meter rates of the New England Water-Works Association and in some of the earlier reports of the Wisconsin Railroad Commission. The New England Water-Works Association has adopted a standard form of meter rates. The schedule includes also a service charge for a $\frac{5}{8}$-in. meter. The output charge is divided under three classifications—domestic, intermediate and manufacturing—with limits of 75,000 and 750,000 gal. per quarter. Quoting from the *Journal* of this society (Vol. 30, No. 4, p. 469) the service charge for a $\frac{5}{8}$-in. meter would be made of three parts, namely:

"(1) Ten per cent. of the average investment of the works in service pipe and meter; (2) one dollar per annum for reading meters, billing and collecting; (3) two dollars per annum for the probable value of unregistered water; for a domestic service charge with a $\frac{5}{8}$-in. meter the ordinary service charge may properly



GALLONS SOLD YEARLY			
Services (Per Cent)	Minimum	Maximum	Average
0-10	4,000	7,000	5,500
10-20	10,000	15,000	12,500
20-30	15,000	19,000	17,000
30-40	17,000	24,000	20,500
40-50	21,000	30,000	25,500
50-60	25,000	40,000	32,500
60-70	27,000	53,000	40,000
70-80	35,000	68,000	51,500
80-90	50,000	92,000	71,000
90-100	86,000	150,000	118,000
Totals	290,000	498,000	394,000
Averages	29,000	49,800	39,400
Average Daily	78	137	108

FIG. 1. PERCENTAGES OF TOTAL METERED DOMESTIC SERVICES USING LESS THAN INDICATED QUANTITIES OF WATER

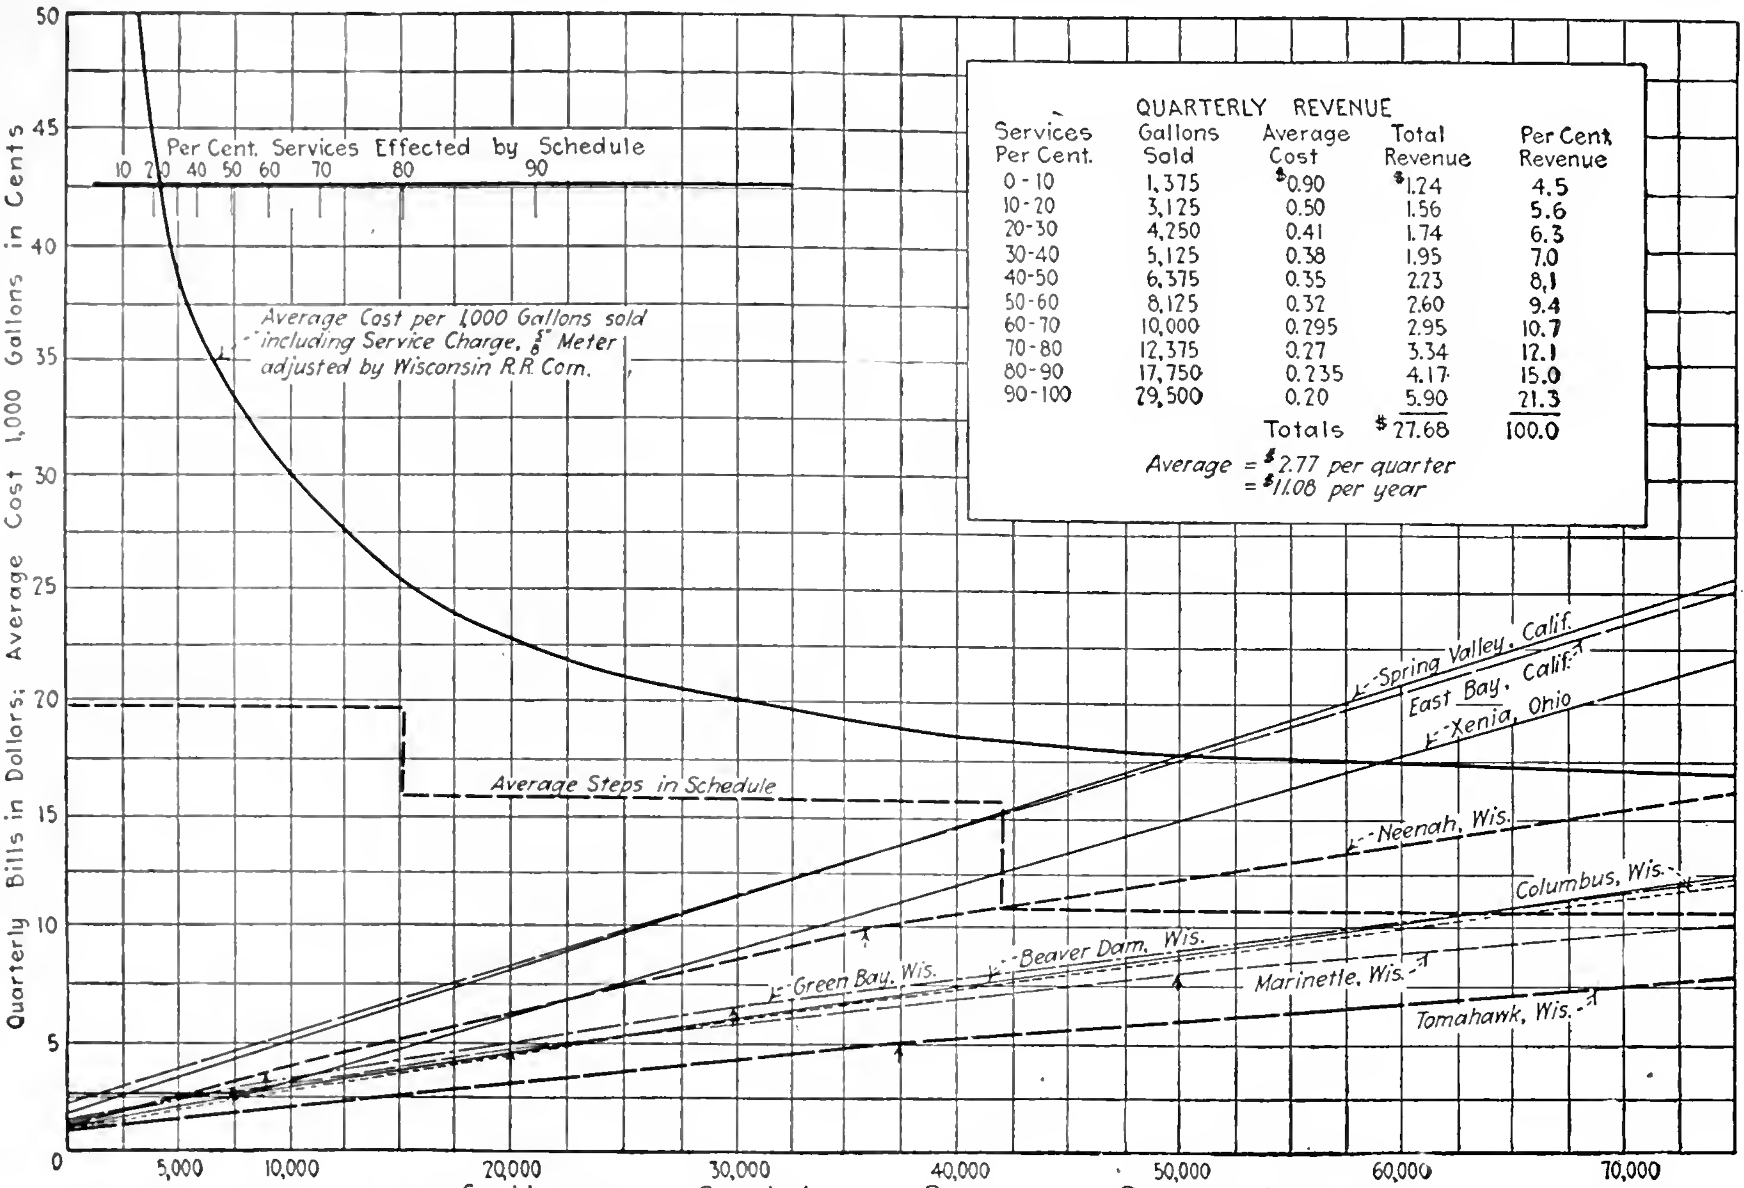


FIG. 2. DOMESTIC METERED WATER REVENUES PER QUARTER AND AVERAGE COST PER 100 GALLONS

be $3, when the service and meter are paid for by the taker; $4 when the meter is furnished by the works; and $5 or $6 where both meter and service pipe are paid for by the works; the lower figure being used where the average cost of the service pipe is under $15 and the higher where it is greater than $15."

It is somewhat remarkable that the service charges determined by the committee of the New England Association and by the Wisconsin Railroad Commission are practically identical, for the amounts are determined in an entirely different manner, especially in regard to the third element which goes to make up the service charge. The New England society's committee determined as this third element the probable value of unregistered water. The Wisconsin Railroad Commission used elements similar to the first two elements contained in the service charge as developed by the committee, but as the third element of the service charge the commission included the capacity expense of the service rendered.

The writer believes that it is immaterial which method may be adopted to compute the service charge, provided that the output charge is figured consistently.

Many errors have been made in estimating revenue receivable under a meter rate, principally because of the fact that reliable information was not available as to the quantity of water sold under the schedule. This quantity frequently is determined by taking from the total output of the plant a certain allowance for unregistered water. In the writer's opinion such a method of computation frequently is subject to error, because of the fact that local conditions which are not determinable affect materially the percentage of unregistered water, which commissions are prone to underestimate. This is one of the fundamental reasons why rate schedules frequently do not develop the amount of the income which they properly should develop.

The more logical method of determining the quantity of water to be sold is, in the writer's opinion, to determine the quantity of water actually sold in similar communities—provided, of course, that reliable information be not available in regard to the plant in question. Unfortunately, however, but little accurate information is available to show the quantity and distribution of the water sold, particularly to domestic consumers. In Fig. 1 I have endeavored to show on several curves the quantity and distribution of water sold to domestic consumers, using the limitation of 75,000 gal. of water per quarter, specified in the schedule of the New England Water-Works Association. This will generally include from 90% to 95% of all services.

The curve, "Meters Neglected," indicates the sale of water by a plant serving about 9000 persons where the meters have been neglected for about 10 years and where the quantity of water sold obviously is much less than the quantity which reasonably should be sold. The curve, "Population 400,000," on the other side of the diagram, represents the distribution of water sold to a large city. It is obvious that the average quantity per consumer in a large city frequently may be more than that sold in a small city, because the water is cheaper in a large city and there is less incentive to conserve the supply; because frequently several families are supplied by the one service; and because there is a class of wealthy people residing in the large city which is not found in the small city. The curve, "25%

metered," also is distinctive as illustrating the fact that the average sale is considerably larger when a comparatively small part of the total consumers are metered, because naturally meters are placed first upon the services supplying large consumers. The "median line" represents approximately an average between the large and small cities, of which three are shown on the diagram.

In the right-hand portion of the diagram are shown the distributions of the sale to the different percentages of services supplied; also the total yearly and average daily quantities of water actually sold. These quantities are significant in view of the fact that generally about five persons are served by each meter. It is obvious that the actual quantity of water sold per consumer is very much less than is generally appreciated.

In Fig. 2 (see preceding page) I have shown the quarterly bills in dollars and the average cost per 1000 gal. in cents, chargeable to domestic services using less than 75,000 gal. per quarter. The schedules adopted were those as indicated and adjusted by the Wisconsin Railroad Commission, two schedules adopted in California, (*Jour.* Am. Water-Works Assoc., March, 1919, p. 37), after adjudication and one schedule recently adopted at Xenia, Ohio, after adjustment by the Ohio Public Utilities Commission.

The diagram shows considerable divergence in the actual cost of water under the several schedules, but on the other hand there is a marked agreement in four of the schedules of the Wisconsin commission. On the diagram I have shown the average costs per 1000 gal. sold, including the service charge of a ⅝-in. meter as adjusted by this commission. This rate varies from the service charge to about 17c. per 1000 gal. It is obvious that in order to get a similar apportionment or distribution of the cost of water service under a schedule containing a minimum charge, it is important that the first unit charge be very much higher than that usually adopted. For instance, the schedule at Xenia contains a first unit cost of 29.2c. per 1000 gal. and a minimum charge of $9.90. This rate is too low, with the result that there is a marked discrimination in the schedule in the favor of about 20% of the consumers, using from 5000 to 10,000 gal. per quarter. The commission wished to establish a schedule which would earn an average of approximately $15 yearly per domestic service, and it is obvious that the schedule selected is unjust to the small consumer and is in favor of the middle-class consumer, whereas if the form of schedule adopted by the Wisconsin commission had been used these discriminations would not have occurred.

I have also shown on the diagram the percentage of services affected by the different portions of the schedule, and it is of interest to note that 50% use less than 30,000 gal. per year. In the same way, I have shown the per cent. of revenue derived from the services, and it is also of interest to note that 50% of the services provide only approximately 30% of the income derived from domestic consumers. In other words, the lower part of the schedule is important as affecting the majority of the customers, but the upper part of the schedule is important as affecting the revenue earned by the company.

I have also shown that, assuming a sale of water similar to that determined on the first diagram and assuming an average cost of 1000 gal., as determined by the second diagram, the average income per service is about $11 per year, based on the average schedule adopted by the Wisconsin commission. This figure is of considerable interest and value in determining what may be reasonably earned by a plant where conditions are similar to those of the average plant above discussed. It is obvious that the expense of service established in California is about double the average

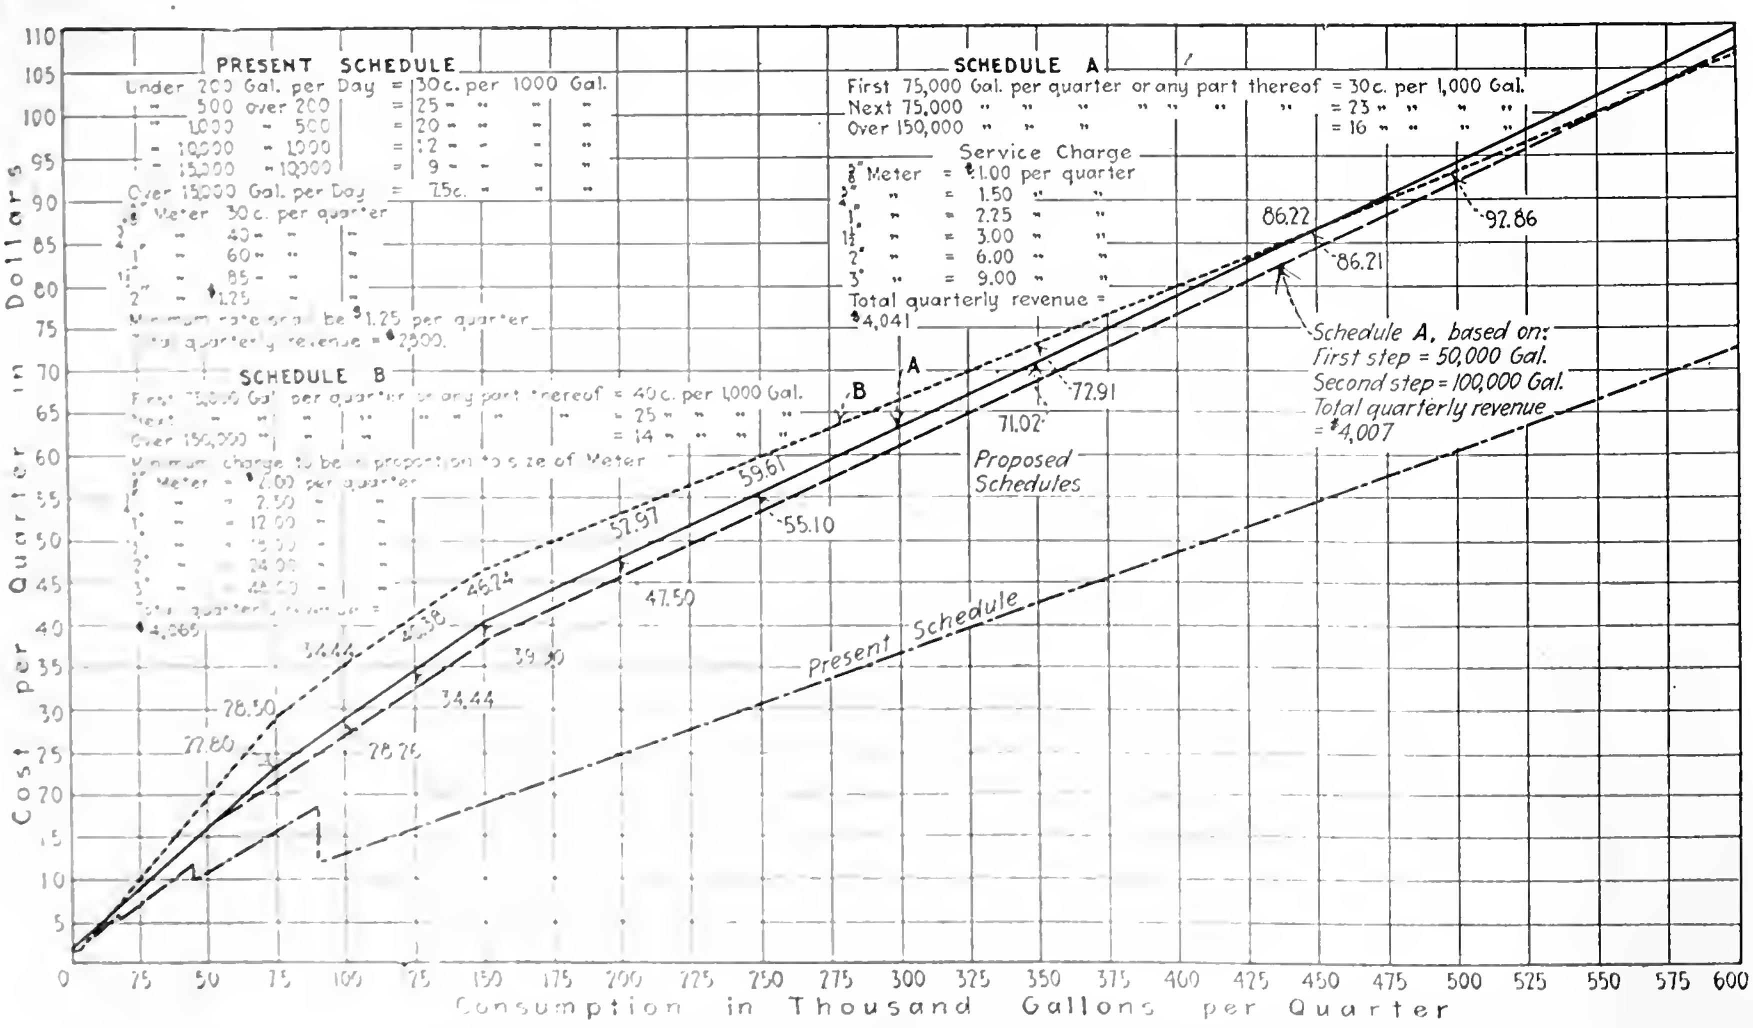

FIG. 3. QUARTERLY BILLS FOR METERED WATER AT GENEVA, OHIO, UNDER PRESENT AND PROPOSED SCHEDULES

expense determined above. The expense at Xenia is about 50% greater than the average, and the form of the schedule could much more properly follow that of the New England committee or that adopted by the Wisconsin commission.

Fig. 3 (see preceding page) shows three rate schedules for a town of about 5000 population. Schedules A and B each are set up to earn practically the same revenue, but schedule A contains service and output charges, while schedule B contains output and minimum charges. Schedule B, containing a minimum charge, is discriminatory, and, in fact, it is practically impossible to make a schedule of this form which is fair to all classes of domestic consumers.

Schedule A should be improved by increasing the service charge and decreasing the first output charge, but there was serious local objection to increasing the cost of service to the small consumer. Schedule B could be improved by increasing the first output charge and by decreasing the quantity of water sold under this charge. Both of these changes would give better balanced schedules and would eliminate obvious discrimination against the middle class of consumer. The present schedule shown on the diagram is similar to many old "sawtooth" schedules in force, and is obviously very unsatisfactory and unfair. It tends to promote waste rather than to conserve the supply.

Interesting Conditions at Plant

Conditions at this plant were especially interesting, because investigation showed that only one-third of the entire output of the station was actually sold. One-third of the output was utilized in sewer flush tanks which were leaking badly and which required a large daily supply in order to make them operate. If rates were determined for this property in the usual manner, by subtracting, say, one-third of the total output as water unaccounted for, and by figuring the rate on the basis of selling two-thirds of the entire output, the actual revenue obtained would be just one-half of the computed revenue. Conditions at this plant are unusual but illustrate the principle which it is desired to emphasize—namely, that rates can be determined only on the basis of the quantity of water actually sold, regardless of the quantity which may be delivered by the system.

In conclusion, the writer believes that the New England form of schedule, with its service charge and an output charge, alone permits an equitable and rational basis of charge for water service. Its general adoption would provide valuable information relative to the actual cost and value of the water service rendered by different properties. Until some standard form of schedule is adopted comparative statistics of water rates will continue to be of little if any value, because the schedules are generally unfair and discriminatory in respect to some of the consumers supplied.

Oil in Chlorinated Water Causes Trouble

Water-supplies in the oil-producing districts of West Virginia are giving trouble, due to the combination of oil wastes with the chlorine. An investigation is being made under Mayo Tolman, chief engineer of the State Department of Health, Charleston, W. Va., to see what can be done to obviate this trouble. Pollution of water-supplies by oil wells is also a matter of investigation by the Kansas State Board of Health.

Handling Iron Ore at the Head of the Great Lakes

How Ore, of Many Different Compositions, From Hundreds of Mines, Is Delivered Rapidly To Boats in Required Analyses

By George H. Herrold
City Engineer's Department, St. Paul, Minn.

On June 20 those members of the American Society of Civil Engineers who will be in attendance at the annual convention in St. Paul and Minneapolis will start on an excursion to Duluth and the Missabe Range. This trip is made the occasion for the description here of one of the little-known details of operation of the iron field.—Editor.

Ore-dock design has been often treated in technical journals, but the system whereby this ore is taken from many mines in variegated composition and delivered to ore docks as required is not so well known.

The iron-ore output of the Lake Superior district was 61,156,732 tons for the fiscal year which ended June 30, 1918, and for Minnesota was 44,537,061 tons, or almost 75% of the total output of the Lake Superior district. Minnesota's output for the year which ended

DIGGING IRON ORE IN A MINNESOTA RANGE

June 30, 1915, was 22,000,000 tons, against a total iron-ore output in Germany in 1915 of 21,000,000 tons. On account of the richness of Minnesota ores, averaging 55% pure iron, it requires only 1.9 tons to produce a ton of pig iron, while the ores of Germany require 2.4 tons of ore. Four million tons of the Minnesota ore in 1918 came from state-owned lands, for which the state received a royalty of over $1,000,000.

This ore lies largely in three districts, known as the Vermillion, the Missabe and the Cuyuna Ranges. The Vermillion ore is all handled by the Duluth & Iron Range R.R. to its docks at Two Harbors on Lake Superior. The Missabe, by far the largest district, is tapped by four railroads, with docks at Duluth and Superior. The Cuyuna Range, the smallest and least developed, furnished 2,588,000 tons for the fiscal year which ended June 30, or an increase of 658,000 tons over the year previous. The haul to the Head of the Lakes is from 70 to 100 miles. The haul to St. Paul on the Mississippi River is 110 miles.

A view herewith shows a typical ore dock, the design of which is fairly well standardized. One of the largest of such docks, for instance, is 2304 ft. long, with 384 pockets of 300 tons, or six cars, capacity each. Its height is 80 ft. above the water surface and on its top are four parallel delivery tracks from end to end. The dock is partitioned along its center line with the pockets opening on either side. The cars, pockets and boat hatches are standardized. The ore car, 24 ft. in length,

DUMPING ORE ACCORDING TO ANALYZED COMPOSITION INTO BOATS AT DULUTH

has an unloading mouth of 8 ft., the pockets are 12 ft. wide, the boat hatches are 24-ft. centers and the ore chutes are 12-ft. centers. A boat can take ore only from alternate pockets without shifting its positions; a cargo for any given boat is therefore placed in alternate pockets. There are over 400 boats in the ore-carrying trade, with capacities of from 5000 to 13,500 tons each.

The ores of the different mines are divided into groups having certain outstanding characteristics, each group having a guaranteed or set analysis, and contracts are made on the basis of these groups. A mine may take out ore belonging to one of these groups, or its ore may have to be mixed with the ore from other mines or an ore of different grade from the same mine, to maintain a group analysis. From the mines, where cars are loaded in open pits or at shafts and switched to the holding yards, samples, usually in units of five cars, are taken to the laboratory, where they are crushed and tested, and a record is made of this unit, giving the car numbers, the name of the mine, the sample number and the analysis. In addition to the iron content, a determination is made of the phosphorus, silica, manganese, alumina, lime, magnesia and sulphur.

A "block" is the name given to a cargo of ore in process of formation, and is built up in a certain number of odd- or even-numbered alternate pockets at the dock. A "hold" is ore which cannot be assigned to any group or "block" because of being off grade, and is held in cars assigned to certain tracks or sections of track, according to grade, to be held for further disposition. "Blocks" and "holds" are designated by number, and no two numbers may be mixed without instructions from the laboratory. As each unit of five cars is weighed at the yard, its waybill receives its "block" number or "hold" number. If the unit belongs to a "block" it is switched to its proper track, and a train is soon made up, sent on its way to the dock, and unloaded. Here the actual tonnage and analysis are carried forward cumulatively until the "block" contains a mixture of ore, built up mathematically, which will have the proper group analysis. By this method units of five cars have been combined one with another and built up until the group analysis is reached. A boat takes, if possible, an entire "block" or all of two or three "blocks," in filling out cargo, for the mixture is mathematical, and a part of a "block" might run short or exceed the average analysis of the whole "block," and, while mixed mathematically, rather than actually, in the dock, it becomes actual after running through the chutes, being spread from near to far side, back and forth, to trim the boat. "Holds" are later ordered to the dock to raise or lower the analysis of a "block" which is running off grade.

All vessels must be loaded in the order of their arrival, and the tonnage and grades for each vessel must be given to the mines before they can begin to figure the "block." There are as many as 40 vessels on the list at one time, and, as many of these carry coal, the time required to unload must be taken into consideration in figuring the time they will arrive at the dock. A thorough knowledge of all lake boats, their capacities and draft and the conditions under which they can unload and load, is a part of the education needed by a dock superintendent or agent. As a road can handle, for instance, up to 125,000 ton in 24 hours to the yard, and the storage is 250,000 tons, and ore boats can take from 5000 to 13,500 tons of ore of any one of a possible 25 standard groups of grades of ore, the mines laboratory must block out the ore 24 to 48 hours in advance of the arrival of a boat, to insure the ore being ready for loading when the boat docks. Not only must ore be ready for loading when the boat docks at its assigned position at a certain dock under certain numbered pockets, but to the master of the vessel must be given the time required to load so he may know his leaving time. The average time of a boat at dock per one thousand tons loaded is one hour and 12 minutes, the average actual time loading is 38 minutes.

At the laboratory the unit is the pennyweight or gram. At the switching yard it is a unit of five cars of approximately 50 tons each, or 250 tons, and at the dock it is a "block," averaging 175 cars, or 8750 tons. Here is a mixing process carried on, on a mammoth scale, done accurately and expeditiously without delay to train or boats. The ores are sold under a guarantee to maintain within a fraction of 1% the chemical analysis of any group or grade. The operation requires skill, assurance and quick action, by men trained to keep accurate figures and accounts, and it is very rare to have serious mistakes occur in the handling of these immense quantities of ore.

Cedar Lake Landslide Damage Suits

The large slide that occurred on the hillside below the Cedar Lake reservoir of the Seattle water-works on Dec. 22, 1918, has led to the bringing of suits against the city for property damages. It is expected that hearings will be held during the summer.

Underwater Construction of Outshore Launching Ways

Speed and Economy of Work at Bristol Justified Choice of Diver Method in Place of Cofferdam Construction—Special Rig for Use in Placing Pile Caps

By E. D. Buel
Engineer for John Monks & Sons, Contractors, New York City

REMARKABLY low costs were recorded in the construction of the underwater or outshore portion of the shipways at the Government fabricated-ship yard at Bristol, Penn., operated by the Merchant Shipbuilding Corporation. The method employed here differed from that used by the contractors at the two other Government yards, at Hog Island, Penn., and Newark Bay, New Jersey.

Five contractors built the 50 shipways at Hog Island, and one contractor built the 28 at Newark Bay. Thus, seven contractors were engaged practically at the same time in constructing 90 shipways. Six of them elected to construct the outboard portion by the cofferdam method, while the contractor for the Bristol work decided to use an underwater method, employing divers. The marked predominance in favor of the cofferdam method caused some anxiety on the part of the engineers of the Emergency Fleet Corporation as to the wisdom of the choice of the Bristol contractor, with respect to economy and time of completion. On discussion of reasons, however, they allowed the contractor to proceed on his own lines. The ultimate success of the method fully justified its adoption.

Capped pile bents covered with a plank deck and carrying the longitudinal launching-way timbers constituted the work which was to be built. It is shown clearly in the drawing, Fig. 1, in inspecting which it is to be understood that the concrete-slab construction continues to the right, up the slope of the building berths. The slab construction extends from Sta. 0 at the head of the way to Sta. 3 + 10, while the timber-bent work extends from 3 + 10 to 4 + 84. There are 26 bents of 17 piles with 70-ft. caps 12 x 14, and 11 six-pile bents with 7-ft. caps 12 x 16.

There is a tidal range of 5.9 ft. at Bristol. In the spring of 1918, when this work was carried out, however, the water seldom went below El. 1.5, mean low water being 0. By taking advantage of low-water stages it was possible to cut off and cap the first seven bents. There remained in the 12 ways 4668 piles to cut off below water, 228 long caps, 264 short caps and about 350,000 ft.b.m. of decking to be placed under water.

For cutting off the piles a floating piledriver was fitted with a circular saw suspended on an arbor and driven by a 40-hp. motor, fed by current from the shipyard's power plant. The saw, shaft, arbor and necessary attachments were bought for about $450, and the motor was borrowed from the yard machine shop. The last pile in the shipways was driven Feb. 22, 1918, and pile cutting under water began Jan. 30, while the river was still frozen over. The piledriver was compelled to break its way through the ice, and in fact was hampered and impeded by floating ice throughout its period of service.

Although the machine was compelled to work from the outshore end and could operate only at water stages high enough to float it over the piles already cut, it proved economical and efficient in operation. The saw could work only three to four hours a day, but it cut through a pile in 40 sec.; a good day's work was 240 piles cut, and at this rate over 20 days were required to cut off all the piles. The pile cutting proved to be the simplest task of those involved in constructing the underwater bents.

By far the most difficult task was the staylathing or drawing into line of the 14 outshore bents of each shipway. This work had to be performed by the divers. The piles in each row were drawn into alignment by 6 x 12 yellow-pine clamps connected by specially designed clamp screws. These had to be applied below the elevation of cutoff, which was from 4 to 10 ft. below the surface of the water, depending upon the tide. The inner pile rows could not be staylathed, as the elevation of cutoff was too close to the river bottom to permit moving the piles; however, the alignment of the rows was excellent, the driving having been done with great care.

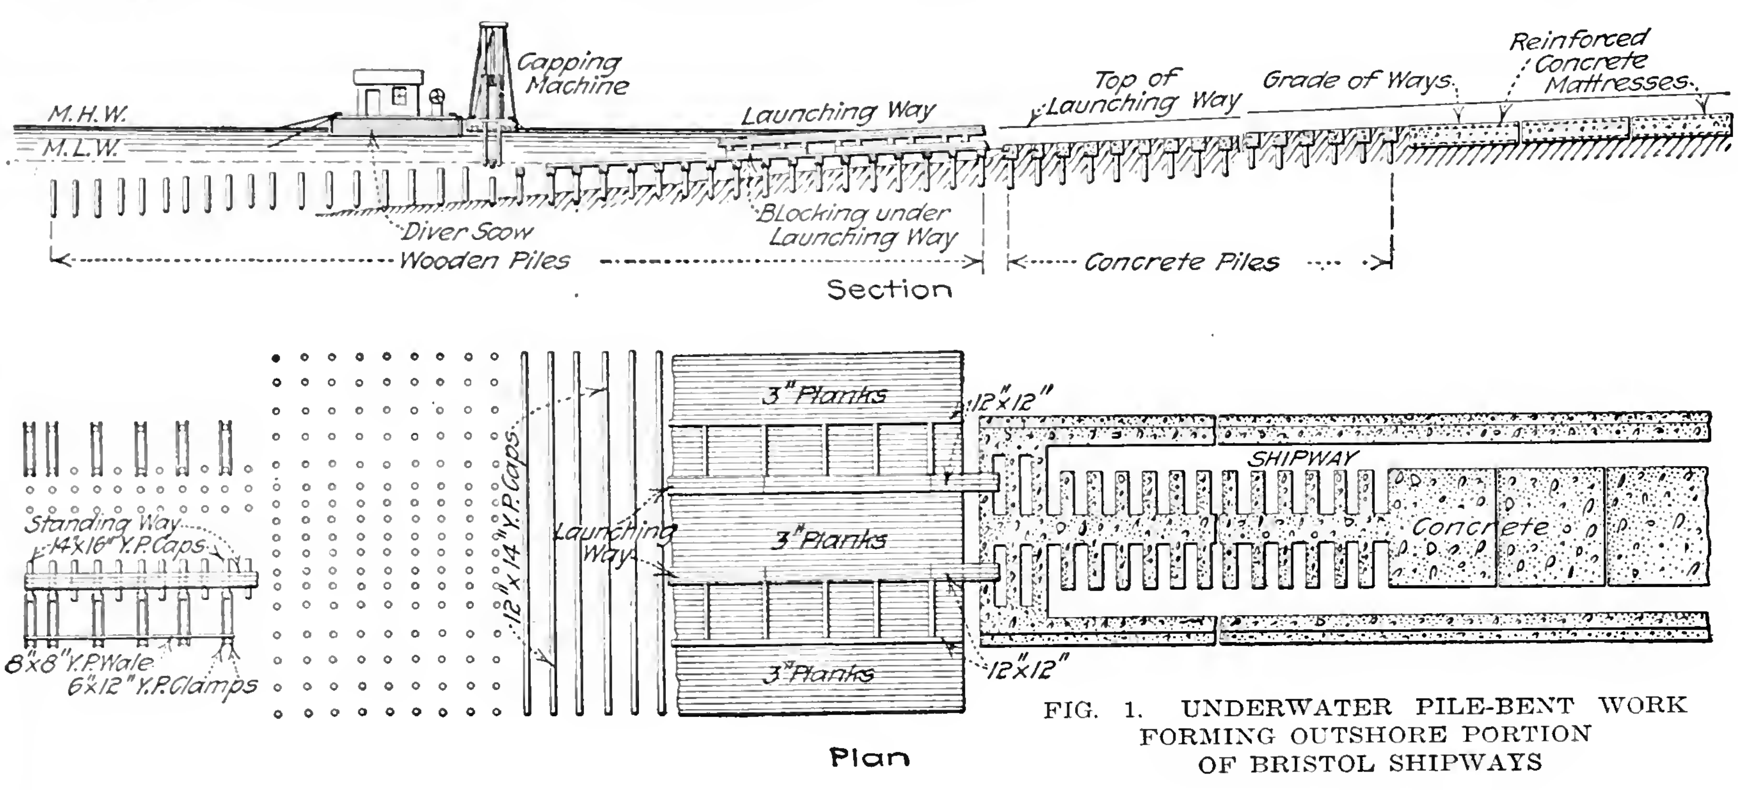

FIG. 1. UNDERWATER PILE-BENT WORK FORMING OUTSHORE PORTION OF BRISTOL SHIPWAYS

Several obstacles made the staylathing extremely difficult work: The rather shallow depth of water in which the divers were working, the ice conditions, and the fact that on account of the low temperature the divers had to wear heavy rubber mitts which hampered

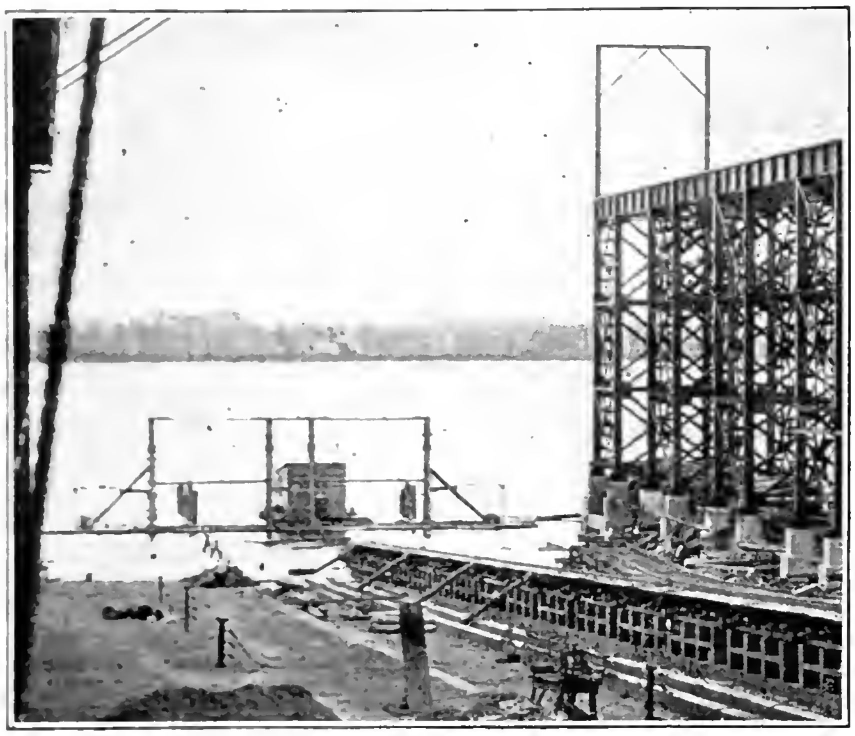

FIG. 2. PILE-CAPPING RIG IN WORKING POSTION OVER LAUNCHING WAYS

their work. A force of 12 divers was employed, the men working in pairs. Two divers averaged four short rows or one-half of a long row of staylathing in an eight-hour day. The total staylathing, therefore, required 210 diver-days, or 17.5 days' work for 12 divers.

In placing the 12 x 14 caps, which were to be fastened to the piles by 1-in. driftbolts 20 in. long, it was necessary to hold the caps down while lining them up and driving the bolts. Four pile-capping rigs were built to facilitate this work. They consisted of floating stages on which were erected gallows-frames supporting spuds weighted with railroad iron. As they were built of timber which was afterward used in the launching ways, the cost of each machine did not exceed $250. A view of one such rig in place over a pile bent is shown by Fig. 2. The construction of the machine is shown in the drawing, Fig. 3.

A full-length cap, 70 ft. long, of 12 x 14 timber, was framed on shore, floated into position, sunk by means of the capping machine, and then scribed by a diver, who marked the position of each bearing pile on the under side of the cap with a scribing knife. Then the cap was floated ashore and, elevations having previously been taken on each pile in the row, the cap was framed by dapping or shimming when necessary to bring it to an even bearing on all piles, and by bolting 6 x 12 fishplates on the sides in cases where one or more piles were slightly out of alignment, in order that the load should be distributed over the full bearing surface of each pile. Holes were then bored and the driftbolts driven through the caps. The cap was again floated to place and sunk on top of its bent. A diver working from each end would place a pipe over each driftbolt in succession, the pipe extending above the surface of the water, and dock builders working on the floating stage of the machine would drive the bolts home by means of weighted rods inserted in the pipes.

Each cap, after it was placed, was carefully inspected by a master diver to determine that it had a full bearing on each pile and that the drift-bolts were in each case driven home. Only very few caps had to be wedged up and reframed.

Two divers, assisted by six dock builders, would place three long caps or eight short caps in an eight-hour day. It is estimated that all the caps required 318 diver-days and 954 dock builder-days.

The decking was assembled on shore into platforms of suitable size to be sunk and spiked by the divers.

Assembling the total labor and plant cost of completing the outboard portion of the 12 shipways, the sum is found to be $33,919, itemized as follows:

COST OF LABOR AND PLANT, EXCLUDING MATERIAL AND PILEDRIVING, FOR OUTBOARD PORTION OF TWELVE SHIPWAYS AT BRISTOL

Divers, tenders and their equipment	$22,705
Dockbuilders assisting divers	7,824
Cutting off piles	1,890
Pile-capping and cutoff machines	1,500
Total	$33,919
Total per way	$ 2,826

It is estimated that the cofferdam method would have involved an expenditure of about $4920 per shipway for merely driving and pulling the steel-pile cofferdam, exclusive of the cost of piling, pumping and labor of cutting off and capping the bents. This applies to conditions at Bristol; possibly the design of the ship-

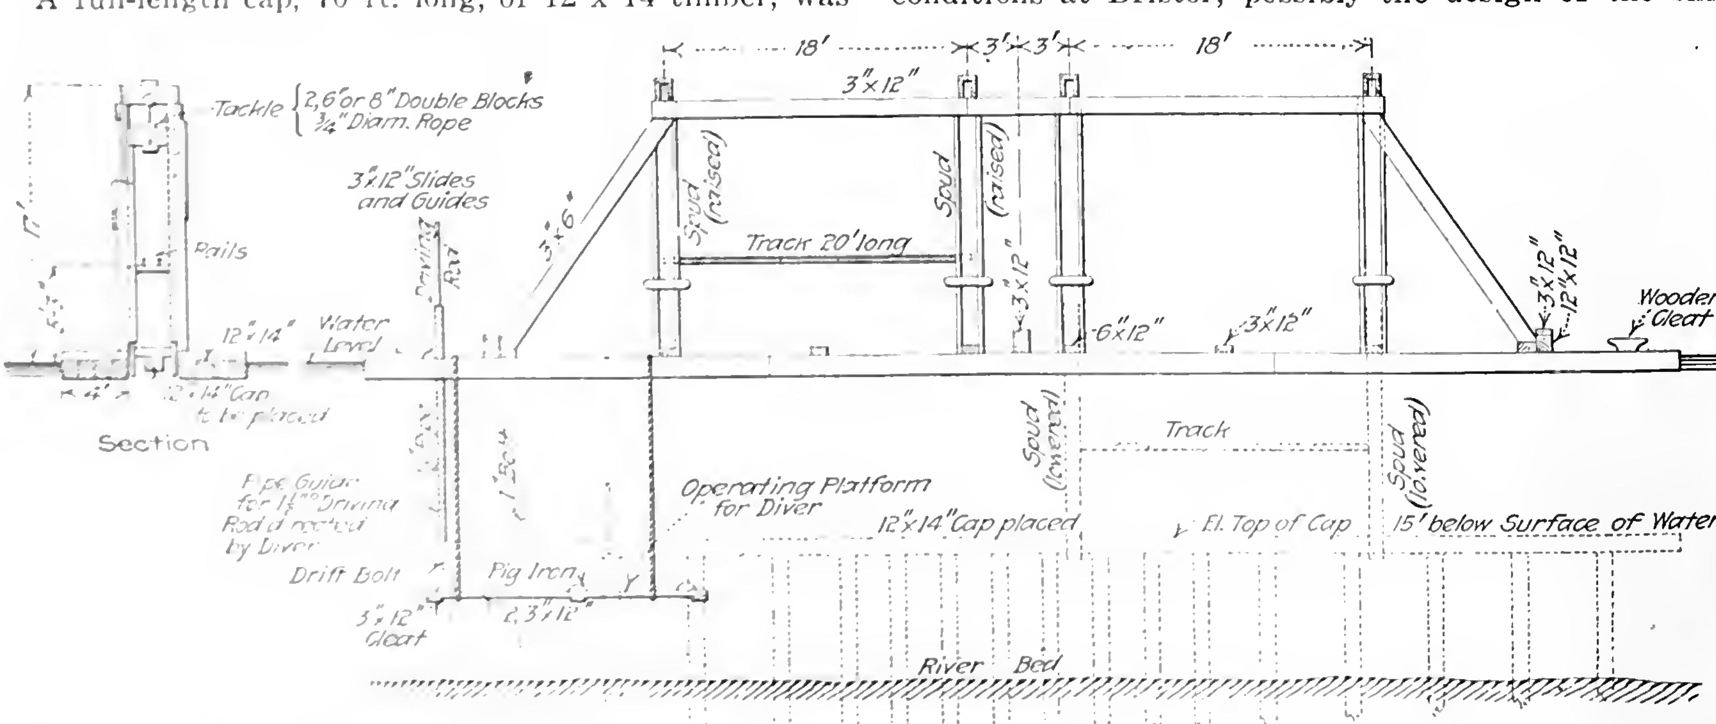

FIG. 3. PILE-CAPPING RIG WITH FLOATING PLATFORM, WEIGHTED SPUDS, DIVER'S PLATFORM AND DRIVE PIPE

ways at the other yards would not require as extensive a cofferdam, and in the absence of reliable figures on the cost elsewhere it is not intended in this discussion to draw any comparisons.

It is the purpose of the preceding to encourage engineers who have a prejudice against underwater construction to believe that this class of work can be handled economically, especially in these days when the wages of divers have not increased in proportion to the pay of other classes of labor. The capping machine is a very simple mechanism, as the photograph reproduced in Fig. 2 shows, and it proved very efficient.

By May 15, 1918, the work on all 12 shipways had been completed. John Monks & Sons of New York were the contractors. Though all of the work was carried on under the most adverse weather conditions, it is fair to summarize the whole case by saying that the final costs were at least 50% less than those which the cofferdam method would have involved, and the Bristol shipways were completed before those at the other two yards.

Council Bluffs Water Treatment in 1918

Substantially the same amount of money was spent for treating the Missouri River water by the water department of Council Bluffs, Iowa, in 1918, as in the previous year, despite the fact that chemicals cost slightly more per pound. The water is clarified by sedimentation, lime and alum coagulants, and sterilized by liquid chlorine. The average turbidity of the river water was 2380 p.p.m., of the settled water previous to coagulation, 1570, and of the final product, 11. Bacterial counts at the same points were 47,760, 1223 and 76. B. coli are always present in 1-cc. river samples, in 92% of the 1-cc. settled samples, and 6% of the 1-cc. treated samples. The 16 gr. per gallon of alum used cost $26.20 per ton, the 0.7 gr. per gallon of hydrated lime, $14.90 per ton, and the 0.258 p.p.m. of liquid chlorine cost 15c. per pound. The total cost of chemicals per 1,000,000 gal. was $4.06. S. L. Etnyre is superintendent.

Supporting Blast Furnace While Replacing Foundation

Well Braced Timber Trusses and Old Crane Girder Utilized—Cracked Brickwork Renewed by Concrete, Using Skip Bridge

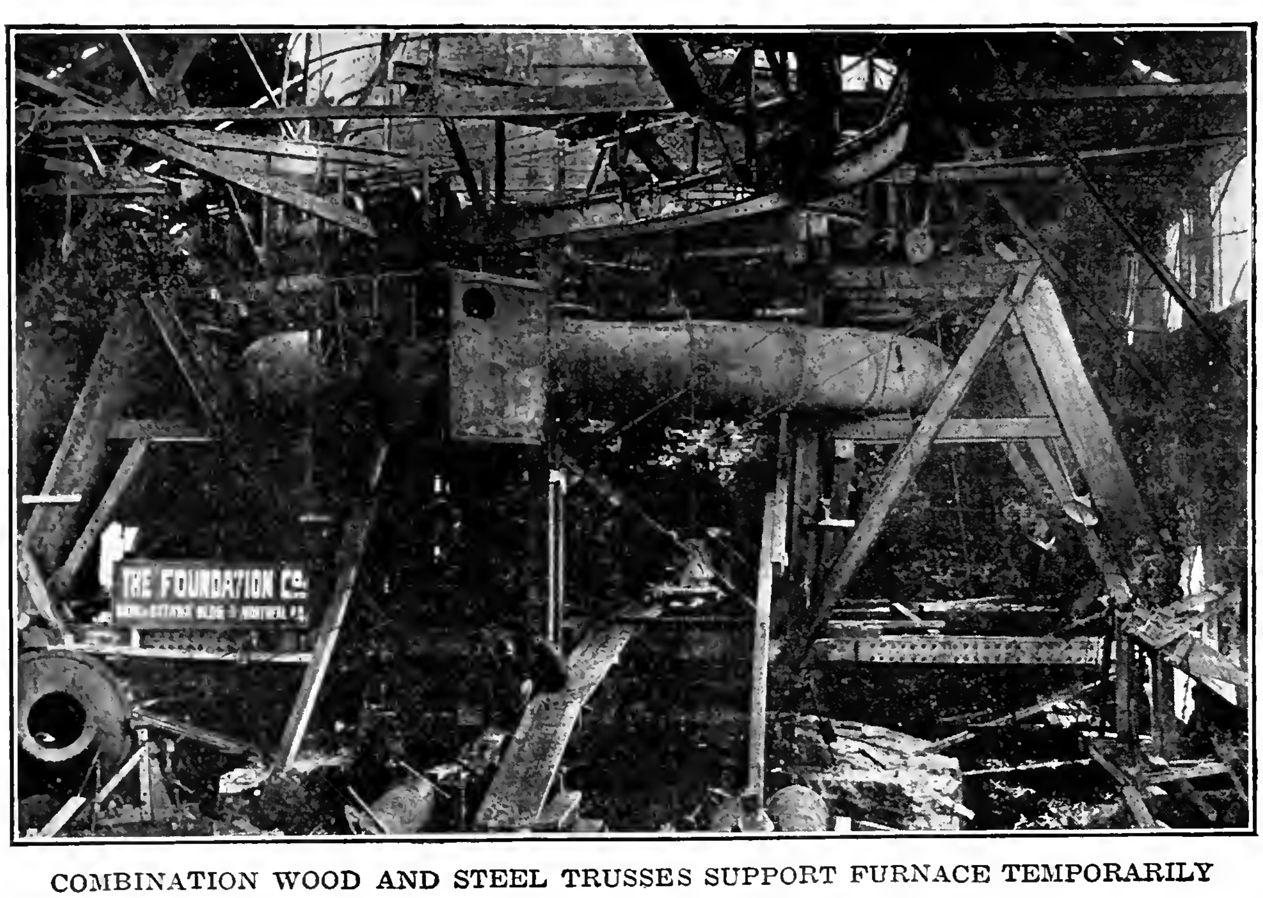
By C. W. Lush
The Foundation Co., Limited, Montreal, Can.

Renewal of the foundation under a blast furnace without disturbing the shell was recently accomplished for the Dominion Iron & Steel Co., at Sydney, N. S., which operates six blast furnaces. These are relined and remodeled in accordance with a schedule providing for the continuous operation of at least three, and generally four, furnaces. During the remodeling of No. 3 furnace the foundation was found to be badly split and veined with iron, and in order to provide permanent support it was decided to install an entirely new foundation instead of reinforcing the damaged one, as was first contemplated. A contract for this portion of the work was therefore made and work started early in July, 1918.

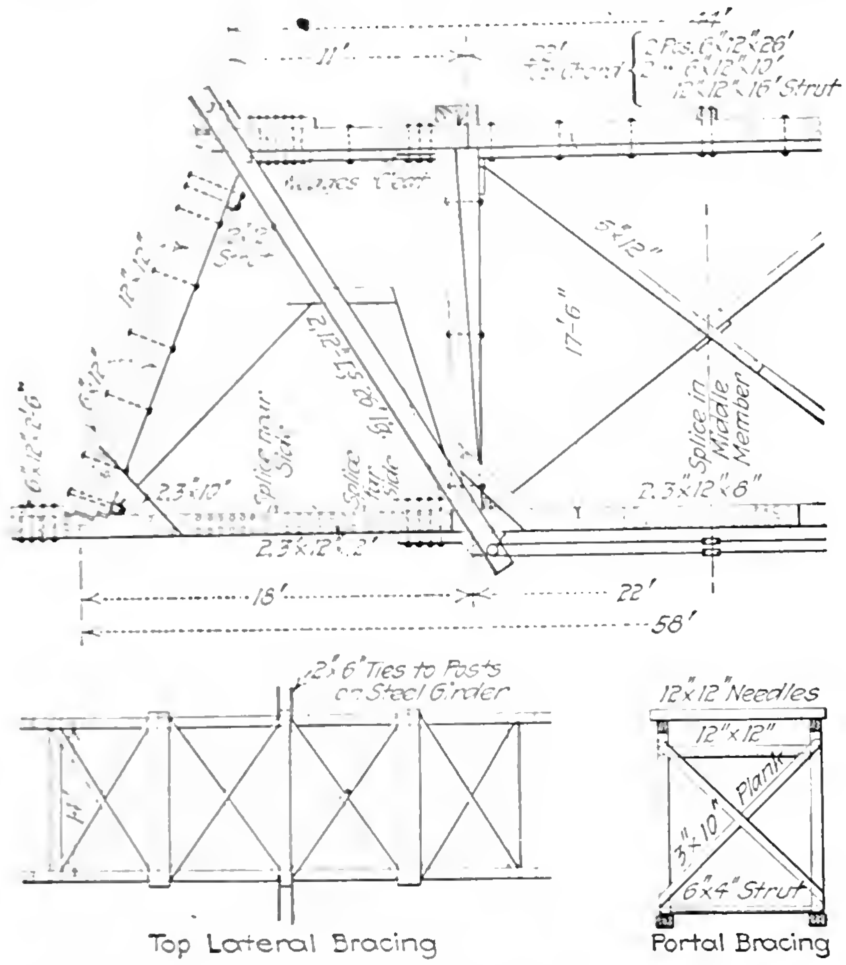
At this time the lining, bosh, hearth jacket and piping had been removed, and a choice of several methods of executing the work was afforded. The problem comprised the supporting of the furnace shell, bustle pipe and column heads, together with some loading from the bleeder pipes, reaction from the skip bridge and severe wind pressures from any direction of the compass. The contractor was required to maintain all existing structures at practically their original elevations.

Comparative studies of methods resulted in a decision to use two wooden trusses (with steel end diagonal web members) bearing on the side walls of the cast house and taking the load of the furnace at the mantle, as the main supports, while an old crane girder already on the site was utilized to take the wind load transverse to the trusses and to help support the bustle pipe. A general view of the shoring and of the principal physical features affecting the work is reproduced. Unique shoring details resulting in high salvage of material, and the adaptation of the construction details to existing conditions at the work, successfully solved the problems of high material costs and difficult labor situation obtaining at the site. The bolster castings and bearing pins used to distribute truss stresses at panel points were detailed to be available later for use as derrick foot-blocks and gudgeon pins.

The two main trusses were first erected, and the load was thrown on them by jacking up under the end bearings. Next the old crane girder, which had previously been placed in position, received its portion of the load by tightening the wedges under the posts bearing on it. The brackets supporting



COMBINATION WOOD AND STEEL TRUSSES SUPPORT FURNACE TEMPORARILY



DETAILS OF COMBINATION TRUSS OF 58-FOOT SPAN

the bustle pipe were then removed from the furnace columns, and the pipe was supported on secondary bents in the main trusses. Finally, the furnace columns and base plates were removed, giving a comparatively clear working space for the necessary excavating.

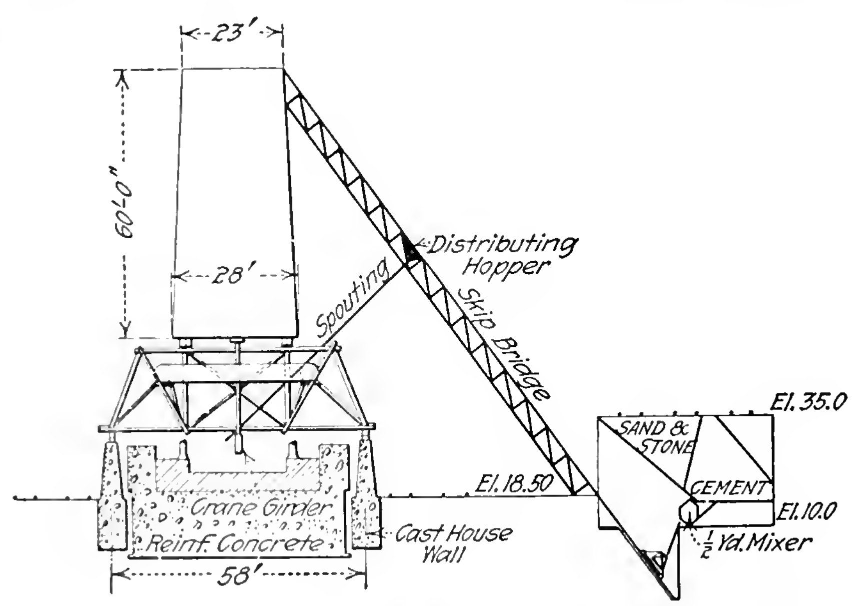
The excavation comprised about 1100 cu.yd. of brick and concrete in the old foundations, 500 cu.yd. of earthwork and a "salamander" weighing 100 tons embedded in the old foundation. The old foundation was broken up by light shots in holes from 2 to 5 ft. deep. One jackhamer working continuously was able to do the necessary drilling. A two-drum engine, through special rigging, operated two dirt buckets simultaneously, and, together with a five-ton crane, handled the material from the pit to three dirt hoppers emptying into cars alongside the cast house. The "salamander" was drilled preparatory to breaking it up, but as it was later found to be only 4 ft. deep it was dropped to the bottom of the excavation and buried under the new foundation, at a considerable saving in time, and without risk of accident to the shoring trusses.

The new foundation consisted of about 1500 cu.yd. of concrete, 140 tons of billet and rail reinforcing and 100M. brickwork. The alternate panels of rails were fabricated on the cast house floor during the excavating period and swung into place, and intermediate rails were erected immediately upon the completion of the concrete footing course.

The concrete for the work was handled by a plant made by adapting the idle coke bins and skip bridge of No. 3 furnace. The general features of this layout are shown in the diagram. Sand and stone were brought in cars on the ore tracks and dumped or unloaded by the ore bridge into the remodeled coke bins having a storage capacity of 125 tons of stone and 60 tons of sand. Cement was unloaded from the cars down a chute to a 250-bbl. storage platform level with the charging hopper. The mixed concrete was hauled up the skip bridge in a car improvised out of one of the dirt buckets and two pairs of spare lorry wheels; it was dumped into a distributor hopper and chuted into the foundations.

When the foundation was prepared for the column bases the columns were swung into place and hung from the mantle ring, the base plates were set under them and jacked up with two 100-ton jacks, and damp grout was rammed under the bases. After the grout was set the shoring screws were slacked off, the trusses were dismantled and the brackets were replaced under the bustle pipe. Finally, the protection ring of concrete was poured around the new hearth brickwork, this being completed Nov. 2, 1918.

The entire operation was successfully finished without any accidents whatsoever, under unusually adverse weather conditions including windstorms with recorded velocities as high as eighty miles an hour. The final settlement of the supported structures was between ¼ and ½ in., the furnace shell being maintained plumb at all times.



SKIP BRIDGE ADAPTED TO WORK OF PLACING CONCRETE

The work was designed and executed by the Foundation Co., Ltd., of Montreal, under the general direction of R. E. Chadwick, Eastern manager, with the writer as superintendent in charge of construction.

Street-Cleaning and Ash-Collection Costs

Unit costs of street cleaning and ash collection for 1915 to 1918, inclusive, for the City of Cincinnati, are published in the annual report of the Department of Street, Sewer and Catch-Basin Cleaning. In practically all the operations, the costs for the year 1918 were much higher than those for the previous years. The superintendent of this department is Fred Maag. The figures are given in the table below:

	1915		1916		1917		1918	
	Unit Cost	Unit Cost with Overhead	Unit Cost	Unit Cost with Overhead	Unit Cost	Unit Cost with Overhead	Unit Cost	Unit Cost with Overhead
Flushing, *squares	$0 137	$0 277	$0 119	$0.241	$0 121	$0.268	$0.120	$0.274
Street sweepings, cu yd	242	.434	.270	.476	.286	.526	.332	.633
Ash collection, cu yd	277	465	.282	468	.299	.515	.344	.613
White wings, 1,000 sq yd	272	.312	.305	.352	.301	.247	.313	.360
Broom gang, *squares	268	324	.243	295	238	282	.264	.305

LETTERS TO THE EDITOR

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Contractor Actually Lowers Bid

Sir—I inclose a clipping which may be of interest to you as something rather unusual in contracting. The reduction in price mentioned will amount to about $1300.

JOSEPH KEMPER,
City Engineer.
Utica, N. Y.

[The clipping to which reference is made is from the *Utica Press* of May 22, 1919. The following indicates the facts in the case:

A contractor who had put in a bid to do some paving, whose bid had been accepted and who had begun work, wrote to the city lowering his bid because he found he could do the work for less and still make a profit. This letter, from the Harry W. Roberts Co., continues as follows: "Certain changes which we have been able to effect in the cost put forward at the time the bids were prepared make it possible for us to authorize a reduction of 16c. per square yard on the pavement prices on both sections of Hart St., and on Gilbert St. In the event of our accomplishing reductions in the cost of any other local paving contract, we propose to offer a modification of contract terms corresponding to our cost saving."—EDITOR.]

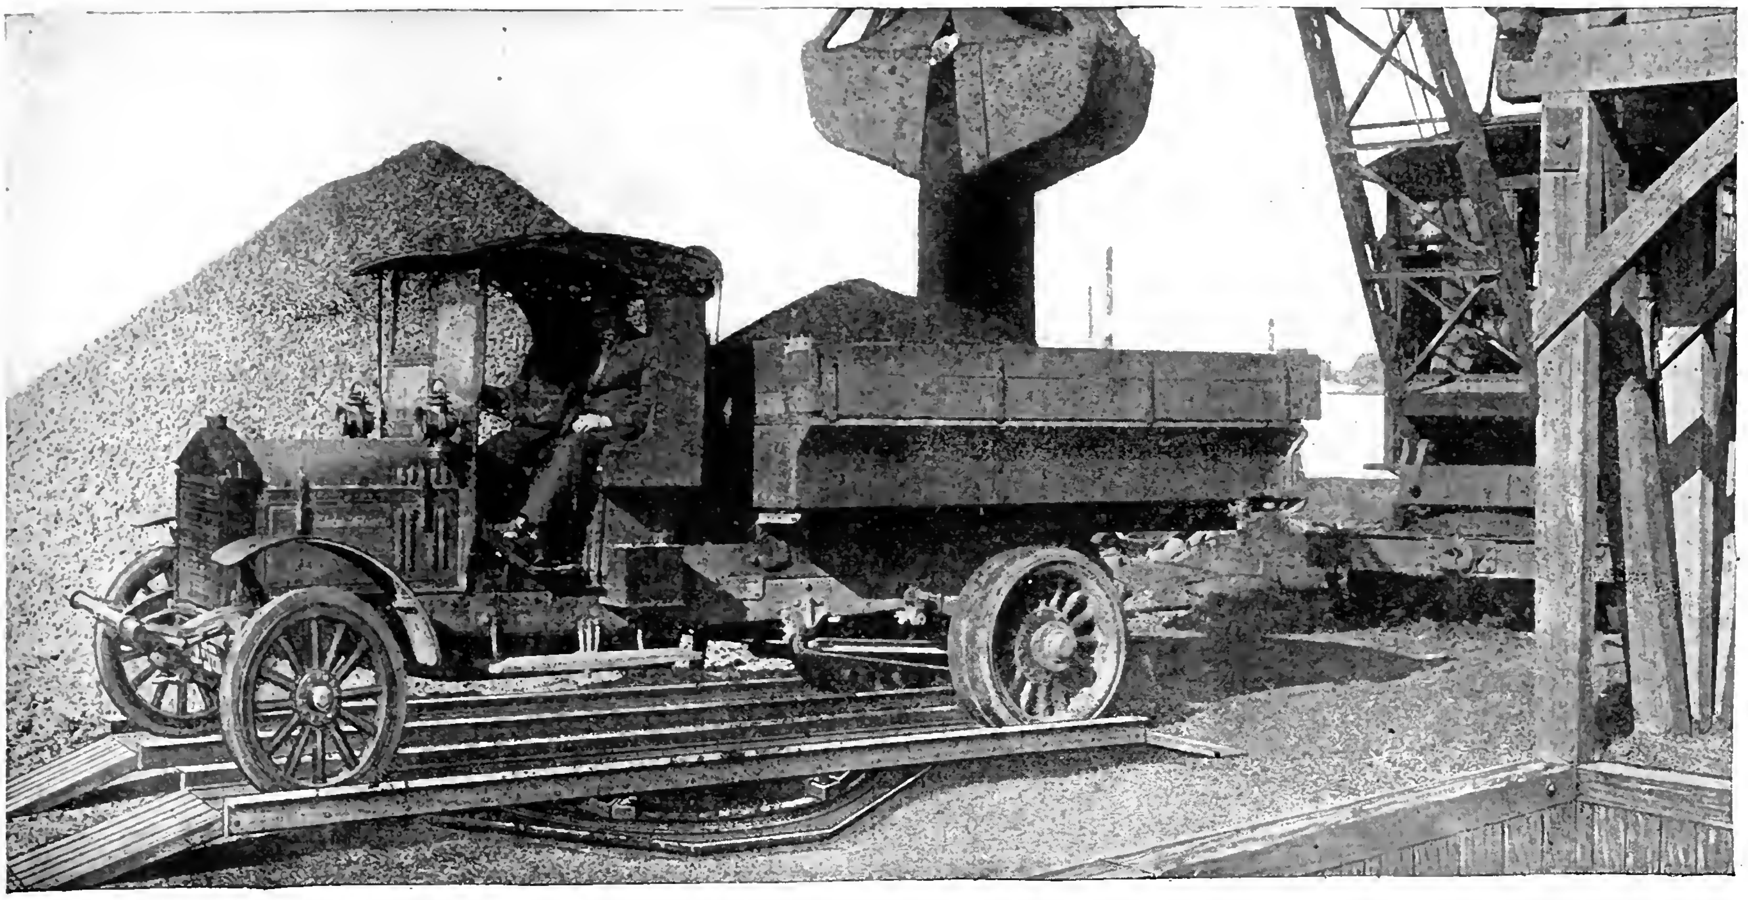
Portable Turntable for Motor Trucks

Sir—The letter of Fred C. Beam, of Lima, Ohio, published in your issue of May 1, 1919, p. 884, under the heading "Who Can Solve this Contractor's Problems?" particularly interests us. Mr. Beam suggests that a portable turntable suitable for use with motor trucks would fill a large need and appeal particularly to operators of motor trucks on construction work. For several months we have spent considerable time and money in the development of just such an equipment, and are now ready to supply a practical turntable of this kind.

Our turntable is the conception of a man who has devoted many years to supplying contractors' equipment and motor trucks for all classes of construction work. He has carefully studied the utility of motor trucks, particularly in connection with road construction. Several years ago he anticipated the need for some mechanical means of turning motor dump trucks when attempts were made to deposit sand and gravel on the subgrade of roads of insufficient width to permit trucks to turn around.

Another practical use for such a turntable is in connection with a revolving steam shovel. When it is set adjacent to and within range of the shovel dipper, a contractor can use motor trucks for hauling away from the shovel. Heretofore this has not been practical except under especially favorable conditions, owing to the difficulty in getting trucks in proper position and started on soft ground. In such circumstances much money has been spent to provide suitable places at which to turn trucks, to obviate the necessity of backing long distances at slow speed, taking undue chances of running over a cliff or into ditches, or getting into deep mud. Those who have not taken unusual precautions doubtless can recite sad tales of delays, pulling trucks out of mud holes and creek bottoms, with damage to subgrade, excessive repair and maintenance bills, excessive wear and tear on their expensive equipment, personal injuries, etc.

Portability on the job and strength successfully to handle loaded dump trucks up to the largest capacity of any make, are, of course, prime requisites for the desired turntable. We believe we have those points well provided for, yet have kept the total weight of our turntable low, nor does it set so high as to cause diffi-



PORTABLE TURNTABLE FOR TRUCKS IS MADE UP IN SECTIONS TO FACILITATE HANDLING

culty in getting on the platform. Our turntable is constructed to permit being pulled along the subgrade by truck or steam shovel or steam roller, without damage to subgrade or machinery. It is made up in sections to facilitate hauling it to the job, and is easily and quickly assembled. It can be furnished either hand- or power-operated.

This turntable will doubtless save much valuable space in material yards, docks, freight yards, etc. It will increase the utility of motor trucks by removing a very serious limitation heretofore encountered by almost all road contractors attempting to use motor dump trucks in the ever-increasing scope of our country's roadbuilding program.

M. D. RIKER,
Vice President, McKiernan-Terry Drill Company.
New York City.

Chart for Solution of Manning Formula

Sir—The accompanying chart for the solution of the Manning formula for the flow of water in pipes or open channels has been so useful to me that it may prove useful to others. It is relatively simple to work with, gives results without bad angles of intersection, even in the extreme ranges, and covers all probable ranges of the four variables. The percentage of accuracy is the same throughout the entire range. My results indicate that the error should be less than 2% in determinations of velocity, or 4% in slope determinations.

Manning's formula, which gives relatively satisfactory results for channels of small or moderate size, and with usual slopes is

$$v = \frac{1.49}{n} m^{\frac{2}{3}} s^{\frac{1}{2}}$$

in which v is the mean velocity of flow in a pipe or open channel, m is the hydraulic radius of channel, s is the slope of the hydraulic gradient, and n the coefficient of roughness, taken to be identical with Kutter's n. Suggested by Robert Manning in 1895, it was published in 1915 in Parker's "The Control of Water."

An incidental advantage in this chart lies in the ease with which different slopes or roughness factors may be compared, and the effect of changes visualized. Thus, if hydraulic radius and roughness factor are known, a horizontal pencil line drawn through their intersection on the chart crosses each slope line vertically below the corresponding mean velocity.

In case it is desired to redraw the chart for practical use, the following instructions may be of service:

The vertical lines form a logarithmic scale, three times repeated, and serve both for hydraulic radius and mean velocity. The horizontal lines are uniformly spaced, and the "slope" lines, s, lie at an angle of 45° to the horizontal. The line $s = 0.01$ starts at the top border line at mean velocity = 1 ft. per second, and $s = 0.0001$ at mean velocity = 0.1 ft. per second. The other slope lines divide the distance between these two into a logarithmic scale, twice repeated, so that the unit lengths of this scale are just half of the main scale.

The roughness lines lie at a slope of three horizontal

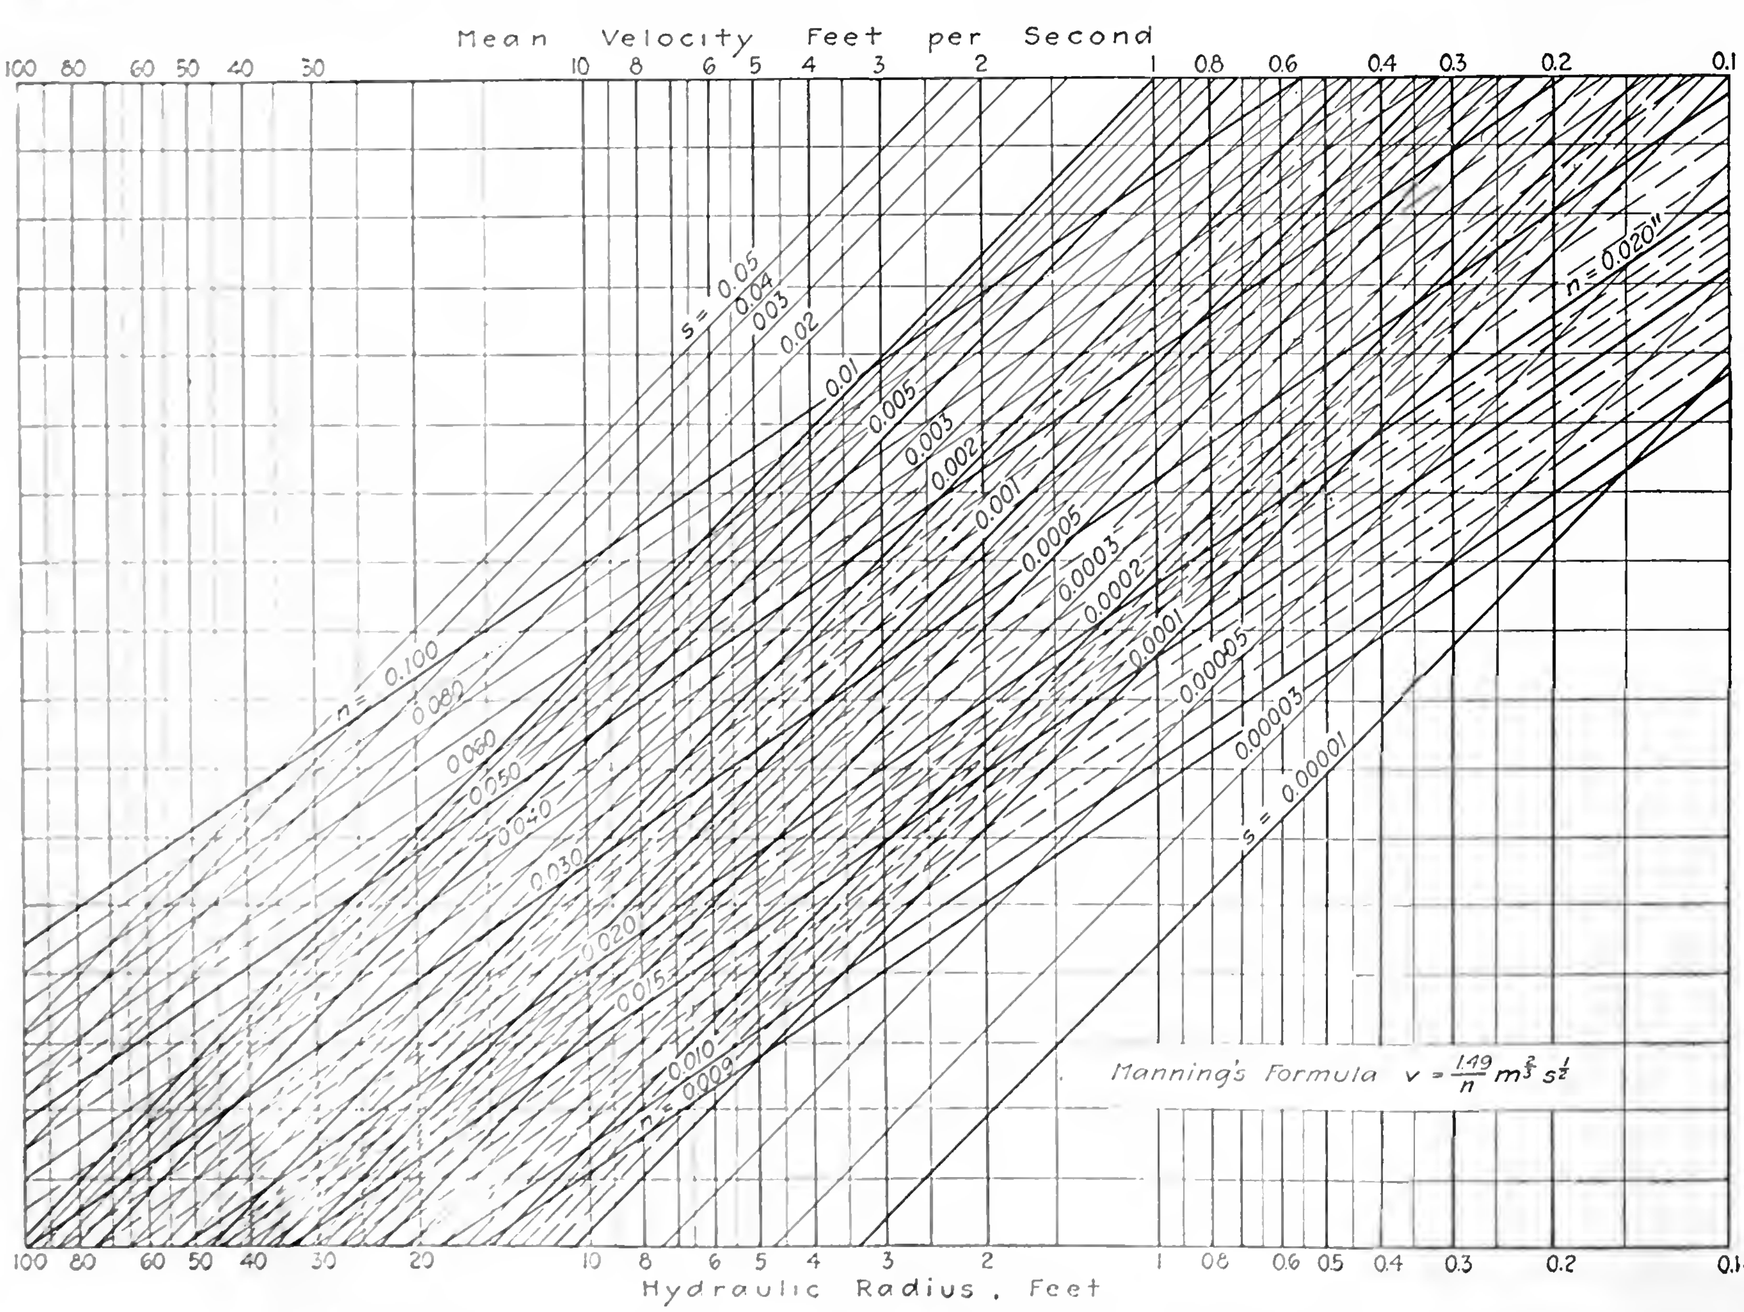


CHART FOR SOLUTION OF MANNING FORMULA FOR FLOW OF WATER IN PIPES

to two vertical, all parallel. They also form a logarithmic scale, and the unit length of this scale, along a vertical line (not at right angles to the lines) is the same as the unit length of the hydraulic-radius or mean-velocity scales. Slope line $s = 0.0001$ intersects mean velocity $= 1$ ft. per second at roughness factor line $n = 0.0149$ (not drawn). This fixes the position of the roughness factor scale. MORTIMER F. SAYRE,

Assistant Professor of Applied Mechanics, Union College.

Schenectady, N. Y.

Plumbers to Be Called Sanitary Engineers?

Sir—Several articles have appeared in *Engineering News-Record* in the past year or so on the subject of what constitutes an engineer. The following is an article which appears in the May issue of the *Valve World*, published by the Crane Co., of Chicago. It is entitled "Why 'Plumber'?"

"Among other features of reconstruction and readjustment we may mention a renaming of the plumber. Whether there is anything in a name or not, we are of the opinion that every plumber in the United States would hold his head a trifle higher and put his trade or his business on a more elevated plane if he were known as a sanitary engineer.

"Let us proceed forthwith to banish the term plumber. It is obsolete or should be. It is lacking in scope. It never can be purged of certain associations that have not tended to give it dignity.

"The *Valve World* will be pleased to attend the obsequies of the term 'plumber' at any time and to hail with hearty acclaim the 'sanitary engineer.' We await only official announcement of the funeral."

The time has surely come when our engineering societies should use their influence to protect the name "engineer." STEWART T. SMITH.

New York City.

Origin of Government Specification for Manila Rope

Sir—In connection with the publication of an abstract of "United States Government Standard Specifications for Manila Rope, adopted Apr. 4, 1918," in your issue of May 15, p. 958, your attention is directed to supplementary information contained in a bureau letter of Apr. 24, 1919, with which mimeographed copies of these specifications were transmitted as an inclosure. It is regretted that no reference was made to the circumstances under which these specifications were adopted, inasmuch as the published article gives the erroneous impression that the bureau is solely responsible for their development. In reality, the joint conference of cordage manufacturers and Government representatives, held Apr. 4, 1918, was the final session of a series of such conferences extending over several months. The conferences were initiated by the Bureau of Construction and Repair of the Navy Department. F. A. Jenks, of the Plymouth Cordage Co., was the conference chairman, and Prof. J. H. Nelson of this bureau's staff served as secretary.

The conferences revised and rewrote an initial tentative draft of manila-rope specifications prepared at this bureau in the autumn of 1917. The initial draft consisted in general of a combination of the diverse specifications at that time in use by various bureaus of the War and Navy Departments, the Panama Canal and the United States Shipping Board. In addition to the use of such specifications, advantage was taken of the results of bureau research into the determination of oil content, the detection of the presence of nonmanila fiber, and the determination of weight, breaking strength and size of rope. The Department of Agriculture furnished the information on which the fiber requirements were based.

An attempt was made to circulate the invitation, to participate in the conference, as widely as possible among the manufacturers of manila rope. The rope manufacturers are chiefly responsible for the final form in which these specifications appear, although their adoption was indorsed by representatives of the Government departments mentioned above. The departments have subsequently used them as the basis for Government purchases of rope. S. W. STRATTON,

Director, Bureau of Standards.

Washington, D. C.

Subdrainage for Country Highways

Sir—Replying to your remarks on my letter in *Engineering News-Record* of May 29, 1919, p. 1080, discussing underdrainage of roads, I wish to thank you for the comment, as a discussion of this question will bring it more directly to the notice of those who are confronted with the necessity of providing a stable roadbed for highways of any kind. In this section of the country many highways are being reconstructed and changed from gravel or macadam to hard surface, long before the bonds issued for first construction have matured.

As to the question whether my letter pertains to "macadam and earth roads almost entirely," I must say that the matter of underdrainage is of the soil. The question of the metal or surfacing of the highway is wholly immaterial; the object is to obtain a subgrade which will most nearly remain in a uniformly stable condition throughout the year.

In the first place, the subgrade for any class of highway must be dry and settled, to permit proper construction. Then the parallel underdrains along each edge of the metal will prevent excess water from reaching the subgrade after construction, and no water can reach it from above because of the hard surface.

Subdrainage for highways is but an application of the principles of drainage for agricultural purposes. The object of agricultural drainage is to remove excess moisture, place the soil in proper condition for the propagation of crops, and prevent heaving of the soil.

If underdrains will prevent heaving in cultivated lands, will they not prevent it in the same soil under a hard-surface road?

I believe that the underdrain will work better if the natural soil, well tamped, is used as backfilling, instead of stone, gravel, cinders or material of like nature which will permit the air current from the tile to escape more directly upward, while to get the full beneficial effect it should also penetrate laterally.

As to tile filling with roots, in our city we have had great trouble with the roots of Carolina poplars finding small cracks in the joints of pipe sewers and filling the pipes. But we have waged a war on trees of that nature and now have very little trouble. M. H. DOWNEY.

Anderson, Ind.

HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Lowering 240 Feet of Submerged Pipe From Scow in One Section

IN LAYING a submerged 16-in. cast-iron water main across the city ship canal at Buffalo, N. Y., the method adopted was to lower it slowly into a dredged trench, from the side of a scow fitted with A-frames for chain falls. The pipes averaged 155 lb. per foot and had bell and spigot ends for flexible joints of the Metropolitan type, in which the lead is retained in the bell when the pipe is deflected. Lengths of 12 ft. were used on the bottom, while 6-ft. lengths were used at the shore ends to give greater flexibility. At each end provision was made for connection with joints of the standard type. At the crossing the canal is 220 ft. wide, with sloping sides; the channel is 100 ft. wide, with 23 ft. of water. A trench 5 ft. wide was dredged to a depth of 30 ft. below water level in the channel, decreasing toward the banks. The total length of the submerged line was 240 feet.

For assembling the pipes, a deck scow 26 x 90 ft. was used, the whole line being made up into three sections. After each joint was calked the pipe was moved within the limits of deflection before another was added. For lowering the pipe line into place a derrick scow and a piledriver were used, the latter being lashed to the bow of the scow. Six A-frames were erected along one side of the deck of this scow, carrying chain falls for suspending the pipe line. There were three lines also from the head of the piledriver. The deck scow, with the sections of pipe assembled, was moved alongside the derrick scow, and the section for the east bank was picked up and suspended from the chain falls on the A-frames. Then the scow was moved forward and the section for the bottom was similarly suspended, the joint between the two sections being then poured and calked. This joint was deflected by lifting with the derrick leg. The section to be laid on the west bank was next added, this being suspended from the three lines on the piledriver.

When the line was ready for submerging, the derrick scow and the piledriver were swung across the channel in line with the trench, with the stern of the derrick against the east bank. The entire line was then lowered slowly until the east end rested on a pile cradle, where it was securely anchored. Then eight leads of 1½-in. manila rope were attached to the derrick scow, and the load was transferred from the chain falls to these lines, the deck ends of which lines were fastened to snubbing posts.

All the lines were then slacked off gradually, allowing the pipe line to sink slowly to its bed. Guides attached to the pipes indicated the various depths as the pipe sank.

Only 3½ hours were required for the whole operation, from the time when the scows were swung across the channel until the pipe rested on its bed; this was the total interruption to navigation. A diver sent down to hammer up all joints found the pipe and joints in good condition. When the shore ends were connected the line was tested by means of a meter. A small leakage was shown at first, but this gradually decreased until it became negligible.

This work was done in November, 1918, at Hamburg turnpike, for the purpose of providing fire protection to an isolated section of the City of Buffalo. It was done under the direction of George C. Andrews, water commissioner.

Other Articles in This Issue of Interest to Contractors:

Bell Slots in Trench Sides Made Use of Narrow Elevator Possible

BELL holes or slots cut in the sides of a trench permitted the laying of nearly two miles of 36-in. pipe in a trench dug by an excavator which could not cut to the full width desired. This work was done by the Bureau of Water at Buffalo, N. Y., under the direction of George C. Andrews, water commissioner, in 1918, to give additional supply to the American Brass Co. and to provide for future needs of the northwestern section of the city.

A trenching machine and power backfiller that were owned by the bureau facilitated the work and reduced its cost on a stretch of 3100 ft. through the grounds of the New York State Hospital, but for the remainder of the distance the work was in paved streets where the machine could not be used.

A 45-in. trench was the maximum that could be cut with the machine, while a 60-in. width was used on that part of the work done by hand. As the narrow width was not sufficient for lowering the pipe into place and at the same time bracing the sides of the trench at the top to protect the pipelaying operations, the following plan was adopted:

Each side of the trench was cut down about 18 in. for a distance of 6 in. back at the top, allowing room for 4 in. of bracing on each side and giving the necessary clearance for the bells of the pipes. Bell holes were then cut out of the side of the trench by hand. The machine cut a trench 7 ft. deep instead of the usual 6½ ft., and 6 in. of blocking was used under the pipe to eliminate

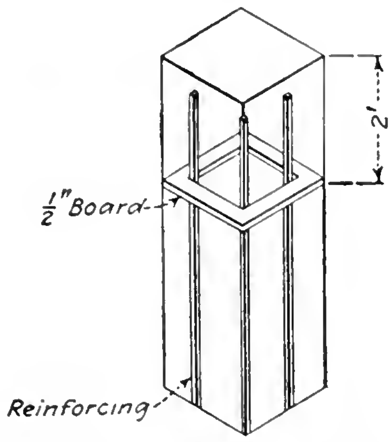
the digging of bell holes in the bottom. This method proved satisfactory and speeded up the work.

Hand labor was employed in handling the pipe, and with a gang of 30 men the excavation and pipelaying proceeded at the rate of about 180 ft. a day. The trenching machine was never worked for more than one-half day, and was kept about two days ahead of the pipelayers. The power backfiller, operated by one man, backfilled the entire trench, with a material saving of labor and time. The greatest number of pipes laid in a single day was 22. The cost of labor for that part of the line done by machine was $4.30 per linear foot, while for the part done by hand labor it was $8. The total cost per foot for the entire line was $23. In comparing the costs of machine and hand labor on this line it should be noted that hand labor was used on paved streets; nevertheless, a great saving is shown by the use of the trenching machine and backfiller.

Two gangs on the work done by hand comprised about 150 men who excavated a 60-in. trench 6½ ft. deep, with bell holes in the bottom, laid the pipe and backfilled, at the rate of 120 lin.ft. per 10-hour day. The pipe was lowered by chain falls and tripod.

Wood Diagram Leaves Top for Concrete Pile After Driving

TO PROVIDE a finished surface at the top of a concrete pile which may be battered during the driving, a special type of joint was used on the Norfolk Army base built during the war. This consisted of a wood diaphragm, made up of ½-in. boards, encircling the reinforcing rods about 2 ft. from the top of the pile, as shown in the sketch. If the hammer spalled the concrete at the top, light charges of powder set just above the diaphragm readily loosened the upper section, permitting its removal and leaving a smooth top, below which no damage extended.

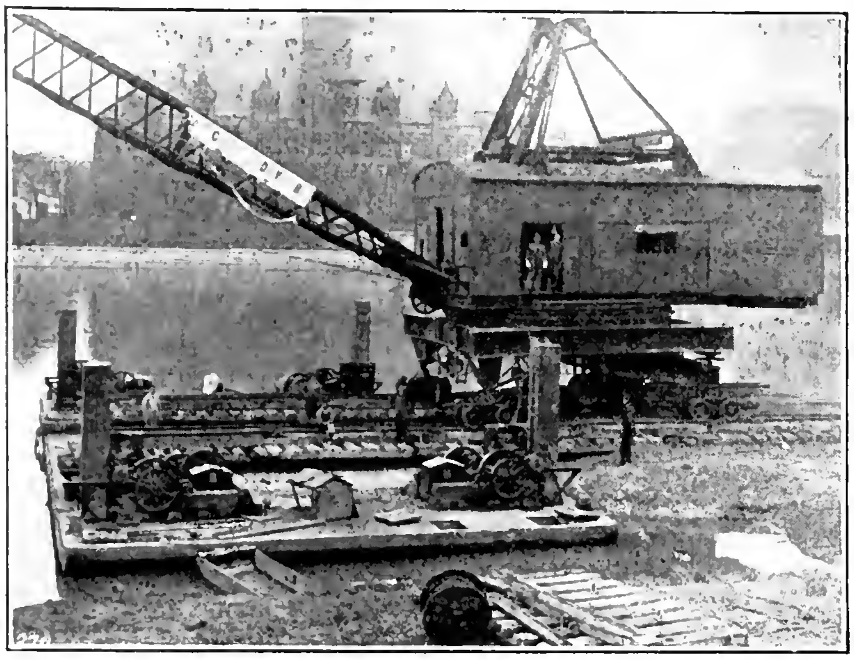


WOOD DIAPHRAGM MAKES JOINT AT CONCRETE PILE TOP

The method was devised by the Raymond Concrete Pile Co., which made the precast piles used in the work.

Dragline Embarked by Grounding Scow

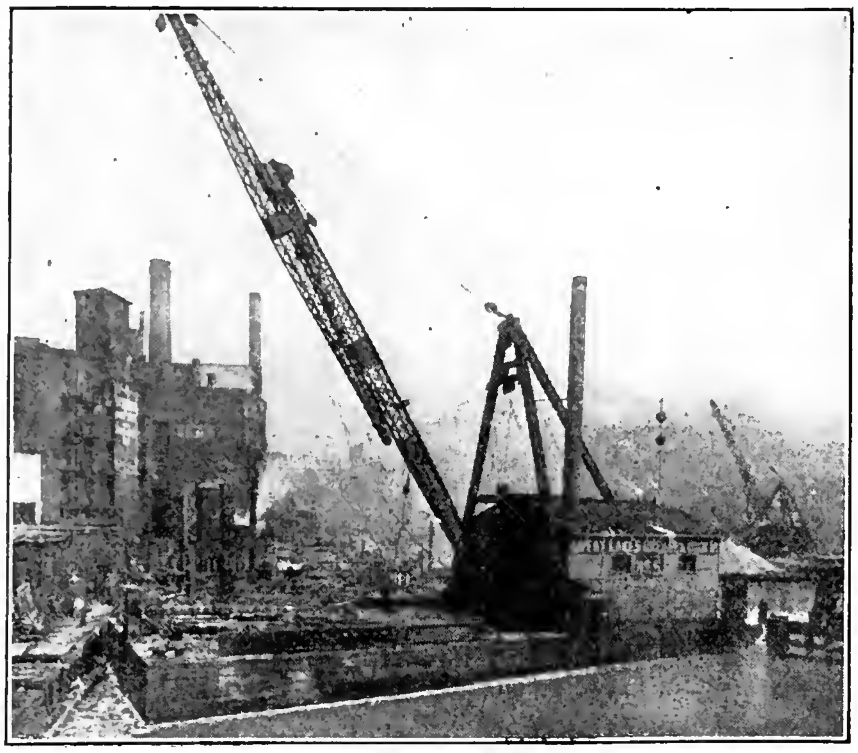
A DRAGLINE excavator weighing over 200 tons was transferred from a river bank onto a scow by the simple expedient, shown by the accompanying illustration, of grounding the scow in a specially excavated shallow slip dredged into the river bank. The dragline dug the slip and dragged its bottom smooth and level, after which the scow was sunk by letting water into it. The shore tracks for the dragline were then extended onto the scow, and the heavy machine was moved into position by its own power. When it was in position the wheels and the underbody were removed, and the dragline was lowered onto and fastened to I-beams on timber sills. The operation was performed at Dayton, Ohio, on the Dayton channel improvement of the Miami Conservancy District. Arthur E. Morgan is chief engineer. Charles H. Paul is assistant chief engineer and C. H. Locher is construction manager.



TRANSFERRING 200-TON DRAGLINE EXCAVATOR TO SCOW GROUNDED ON RIVER BOTTOM

Lengthen Derrick Boom by Second Boom

TO HANDLE 60-ft. 10-ton steel anchor columns in a vertical position, so as to lower them through the pockets of cofferdam bracing, a boom of extra length and strength was required for the steel floating derrick used by the Great Lakes Dredge & Dock Co. at the new Michigan Ave. bridge in Chicago. To secure the necessary length of about 95 ft., a similar but lighter boom for this same derrick was spliced to the main boom as shown in the accompanying view. It was attached by long bolts through timber cross-pieces.



TWO DERRICK BOOMS ARE SPLICED TO MAKE ONE LONG BOOM

The columns handled in this way are embedded in the anchor piers and carry the girders which take the uplift due to the leaves of the bascule bridge.

News of the Week

New York, June 5, 1919

C. M. Holland and Board To Build Hudson Tunnel

Tunnel Engineer Now In Field Charge of East River Work Selected as Chief Engineer

On June 3 the Joint Interstate Bridge and Tunnel Commissions of New York and New Jersey made the final selection of the engineers who are to direct the construction of the highway tunnel under the Hudson River recently authorized by the two states. Clifford M. Holland, now tunnel engineer of the Public Service Commission (New York City), in charge of rapid-transit tunnel construction under the East River, was chosen as chief engineer. At the same time an advisory board of engineers was created, to guide in the decision on the layer problems involved.

The advisory board is composed of J. Vipond Davies, of the consulting engineering firm of Jacobs & Davies, engineers of the Pennsylvania R. R. Hudson River tunnels and engineers and constructors of the Hudson & Manhattan tunnel system; Prof. William H. Burr, former member of a board of engineers which studied the feasibility of a Hudson River tunnel for the Public Service Corporation of New Jersey; Col. W. J. Wilgus, former vice-president and chief engineer of the New York Central & Hudson River R. R., and originator of a tunnel project for freight distribution in New York City in conjunction with a Hudson River tunnel; Col. Henry W. Hodge, consulting bridge engineer and former member of the Public Service Commission of New York City; Maj. John A. Bensel, former chief engineer of the Department of Docks and Ferries, New York City; and E. A. Byrne, chief engineer of the Department of Plant and Structures (Bridges and Ferries), New York City. Mr. Byrne, it is reported, will serve without compensation, while the other members of the board will receive annual retainers of $10,000.

Advisory Committee on Shipping Law Revision Appointed

Revision of the navigation laws in regard to measurement of vessels, standardization, inspection of construction, and other matters affecting the competition of American ships with those of other countries, is to be studied for the Shipping Board by a committee just appointed. The results of the committee's work will be the basis of recommendations to Congress for appropriate legislation. The committee is composed of P. A. S. Franklin, president of the International Mercantile Marine Co.; J. P. Kirlin, admiralty lawyer, New York; H. F. Alexander, ship owner, Seattle; E. E. O'Donnell, ship owner, Boston; H. L. Ferguson, president of the Newport News Shipbuilding & Dry Dock Co.; A. G. Smith, ship owner, New York, and D. T. Warden.

Employment Bureaus

Engineering Societies' Employment Bureau, 29 W. 39th St., New York City.

American Association of Engineers, 29 S. La Salle St., Chicago. Service to members only, but Army or Navy Engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

Engineers' Service Bureau, 57 Post St., San Francisco. Only applications by mail or wire will be considered.

Professional and Special Section, United States Employment Service, 469 Fifth Ave., New York City.

Reëmployment Committee of New York City for Soldiers, Sailors and Marines, 233 Broadway, New York City.

Many Memorial Day Launchings

In celebration of Memorial Day an unusual number of launchings was carried out in the various shipyards of the country on May 30. The most notable performances were made at the two Government fabricated shipyards at Hog Island, Penn., and Newark, N. J. Five 7800-ton ships were launched at Hog Island. The Submarine Boat Corporation, at Newark, launched three 5000-ton vessels; with these it has put into the water 52 hulls since its maiden launching on May 30, 1918.

Elevated Railway Extension, New York City, Begun

Construction of the elevated portion of the Pelham Bay Park branch, Lexington Ave. subway, New York City, began during the past week under a contract executed between the Public Service Commission and the Terry & Tench Co., Inc., for $586,700. The new structure will extend from the present subway terminus at Whitlock Ave. to Pelham Bay Park. Foundations for the columns are already completed.

Power Legislation Once More Before Congress

Three New Water-Power Bills Introduced, and Funds Asked for Power Survey of Entire Country

Legislation providing for the opening up of the tremendous power possibilities of the country has been introduced into the new Congress. The legislation was defeated by the filibuster at the end of the last Congress. Water-power bills in three different forms have been presented to the Senate, and the House of Representatives has passed a rule providing for the creation of another special water-power committee similar to that which worked a bill through the house at the last session of Congress. The three bills introduced in the Senate are by Senator Jones of Washington (Senate 152), by Senator Walsh of Montana (Senate 220), and by Senator Shields of Tennessee (Senate 651).

The movement to obtain appropriations for a power survey of the United States is again under way. The estimates of appropriation presented by Secretary Lane of the Department of the Interior to the last Congress have been renewed, and are now before the appropriations committee of the House of Representatives. These appropriations would permit the Geological Survey to expend $250,000 in studies of power supply during the coming fiscal year. Of this amount $50,000 would be used in a general engineering and statistical survey of the power resources of the United States. The balance of the appropriation would be used for an intensive survey of power possibilities along the north Atlantic seaboard, where the power famine is greatest. Hearings will be started immediately before the appropriations committee of the House.

Federal Industrial Relations Commission Planned

A bill creating a Federal Industrial Relations Commission has just been introduced in Congress. If it is passed, a commission of four would be formed whose duty it would be to promote industrial peace and prosperity by dealing with the causes and conditions provocative of industrial discontent and unrest.

Functions as follows are delegated to the commission: (1) Exert its authority to relieve unemployment; (2) coöperate with Government departments to equalize and regularize employment opportunities; (3) establish standards of industrial relations for Government

departments in employment and purchasing; (4) represent the public interest in labor disputes; (5) promote and develop adjustment boards for the standardization of wages; (6) promote uniform legislation in all matters relating to industrial peace and welfare; (7) establish educational agencies for training administrators of employment; (8) maintain a personnel bureau for rating and listing labor administrators; (9) coöperate with the Departments of Commerce and Labor, and (10) report to Congress a plan for industrial insurance for old age, accident, injury, etc.

Each commissioner would receive a salary of $5000, and the commission would be composed of one employer of labor, one representative of wage earners, one economist, and one specialist in labor administration. One of these must be a woman. The regular term, after a graduated adjustment so that all will not retire at once, is five years.

Secretary of Labor Asks Continuation of Employment Service

Enactment of legislation to provide a permanent public employment service has been requested by Secretary of Labor Wilson in a letter of May 30 to Representative J. M. C. Smith, chairman of the House Committee on Labor, and Senator Kenyon, chairman of the Senate committee.

The Secretary asks that the United States Employment Service be continued as a permanent bureau of the Department of Labor, in charge of a director general to be appointed by the President. The plan embodies the suggestion for full coöperation with the various states.

Bill to Promote Engineering and Industrial Research

On May 20 the Gronna bill for the promotion of engineering and industrial research was introduced into the United States Senate. It provides that the Secretary of Commerce and the National Research Council shall be designated as a national board of engineering and industrial research. No compensation other than actual expenses of the members shall be paid. The board is to appoint in each state and territory a research board of "five engineers or scientists engaged in the development of engineering and industrial science" to have immediate conduct of the research provided for by the act, in their respective states or territories. Board members are appointed for five years, and an executive committee of six is provided for the purpose of coöperation, and to determine whether proposed investigations are new, needful and justifiable. A majority vote of this executive committee is required to authorize any research work along lines clearly outlined in the act. Bulletins are to be published giving results of investigations. The sum of $15,000 per annum is appropriated to the Department of Commerce and also to each state and territory.

Canadian Senate Passes Railroad Bill

Provides for Canadian National Railway Company To Operate Properties for Government Account

The bill incorporating the Canadian National Railway Co., passed by the Canadian House of Commons May 6, was passed by the Senate May 27 and will become law on receiving the assent of the Governor General. The bill provides that the Canadian National Railway Co. shall operate, for Government account, 31 major properties and 14 subsidiaries, included in the Canadian Northern System.

The bill recites that it is expedient to provide for the incorporation of a company under which the railways, works and undertakings of the companies of the Canadian Northern System may be consolidated and, together with the Canadian Government Railways, operated as a national railway system.

It provides that the Government may nominate not less than five nor more than 15 directors, who are incorporated under the name of "Canadian National Railway Co.," stock ownership not being a necessary qualification.

The Government may declare that the company shall have a capital stock, with or without shares, in such amount as may be deemed expedient, vesting the stock with the Minister of Finance. From time to time the Government may entrust to the company the management and operation of any railways or works controlled by the Government.

All expenses incurred in the operation and management of the company shall be paid out of Government revenues and, in the event of a deficit, the amount is to be paid by the Minister of Finance out of the consolidated revenue fund and included in the estimate submitted to Parliament. In the event of a surplus, the amount will be paid into the consolidated revenue fund.

The properties and works of a number of the constituent and subsidiary companies of the Canadian Northern System are declared by the bill to be "for the general advantage of Canada" and therefore subject to Federal and not provincial jurisdiction. Provision is made for the extension of the time of completion of a number of lines which the Canadian Northern System was authorized to construct, for two to five years. The company is given wide powers for constructing and operating transportation systems, for acquiring securities and obtaining advances, and for the issue of bonds, debentures or other securities for new construction.

Chicago Railway Electrification

A 15-year program for electrification of the Illinois Central R.R. at Chicago is to be included in the proposed ordinance for improvements along the south shore. As agreed upon by the railway, the Chicago commission on railway terminals and the council subcommittee on railway terminals, the ordinance is to provide that within five years after its passage the railway will have its suburban service operated by electricity, and within 10 and 15 years will have this extended to its freight service north and south of 12th St., respectively.

To Reinforce Niagara Arch Bridge for Heavier Traffic

Reconstruction of the Niagara railway arch bridge, which carries the tracks of the Grand Trunk Ry. across the Whirlpool Rapids Gorge, Niagara Falls, N. Y., has just been put under way, contracts having been let last week. The bridge as now existing has a designed capacity not exceeding Cooper's E40 loading. Traffic has so increased that reinforcement was thought advisable in order to bring the capacity up to modern loading and meet the growing demands of traffic over the bridge. The principal items of the revision are reinforcement of the floor steel of the main span and the trusses of the approach spans; placing a drainage floor on the railway deck to protect the steelwork and the highway floor; and renewing the highway floor. The cost of the work is likely to run up to several hundred thousand dollars. Contracts for the steel fabrication and erection have been let to the Lackawanna Bridge Co. and Terry & Tench, respectively. The work is being carried out for the corporation, the Niagara Railway Arch Bridge, under the direction of C. E. Fowler as consulting engineer.

Fifth National Exposition of Chemical Industries

The fifth national exposition of chemical industries will be held in the Coliseum and the First Regiment Armory in Chicago during the week of Sept. 22, 1919. As usual, there will be a number of society meetings held jointly with it. For these meetings, to be held in connection with the exposition, programs are in preparation, which include the meetings of the American Institute of Mining and Metallurgical Engineers, the American Electrochemical Society, the American Ceramic Society, and the Technical Association of the Pulp & Paper Industry. The office of the management of the exposition was changed June 1 from New York City to 417 S. Dearborn St., Chicago.

Missouri Road Bond Law Declared Constitutional

By a decision of the Supreme Court of the United States in a taxpayers' suit involving the validity of $3,000,000 worth of road bonds issued by St. Louis County, the Missouri road bond law has been upheld. This law authorizes county officials to issue road bonds and levy taxes therefor upon a vote of county residents. The Supreme Court declares the law to be constitutional. This decision will allow work in St. Louis County, which has been held up for several years, to go forward.

Engineering Council

Observations by National Service Committee

M. O. LEIGHTON, Chairman
McLachlen Building, Washington, D. C.

An Engineer's Unfortunate Experience

Engineers who were enrolled in the Reserve Corps at the beginning of the war will be interested in the circumstances related below. How many engineers had a similar experience? All who did are urged to send a detailed statement to the National Service Committee. If the experience was common the combined testimony may be sufficiently strong to induce Congress to provide for reimbursement. It is not probable that corrective action can be secured on the basis of a few instances. Therefore, the engineers who have knowledge of similar cases and who fail to respond to this invitation may be depriving other engineers who are not so indifferent as to the consequences.

The following letter was addressed to the American Society of Civil Engineers by one of its associate members resident in the Philippines, and by progressive reference finally came to the Washington office of Engineering Council.

The American Society of Civil Engineers,
New York, U. S. A.

Dear Sirs:

As you are doubtless aware, the American Society during the recent war played a very considerable part in obtaining the services of engineers for the Army. Literature descriptive of the Engineer Officers' Reserve Corps was circulated throughout our membership and the society's appeal for men was probably responsible for a very large number of volunteers. In view of this fact, I am taking the liberty of advising you of certain instances in which the War Department, through the Chief of Engineers, seems to have violated the agreement under which the engineer officers were induced to offer their services. I am doing this with the hope that the society may be instrumental in securing legislation that will result in a partial reimbursement to the men for some of the financial loss that they suffered through certain rulings of the War Department.

Among other things, we were informed that reserve corps officers when ordered to active duty would receive the pay and allowance that officers ordinarily do when changing stations. Any number of Western engineers, several of them located in Alaska, applied for commissions in the first Engineer Reserve Corps. After their applications had gone forward the reserve corps was abolished by the War Department. Without receiving any information to this effect these men were telegraphed offers of commissions in the Engineers, U. S. A. They were accepted and ordered to Camp A. A. Humphreys, Virginia, for duty as students. Upon their arrival there they were informed that they would receive no travel allowances at all. The 7c. a mile that they expected was not due them because they had accepted commissions in the regular Army, not in the reserve corps. This was the first intimation that they had as to their new status. Most of the men, particularly those from Alaska, had been to a very considerable expense in traveling, as much as $250 in some cases, and naturally consider themselves unfairly treated.

Another instance, one which covers my own case, occurred as follows: Some 25 or 30 of us entered the service in the Philippine Islands. We were discharged in the States, most of us in the Eastern part. Our discharges came just too late to permit us to catch the December transport for the Philippines, so we were forced to wait for the January boat, which arrives in Manila about Feb. 15. We were thus over two months without pay, our Army pay having stopped on the date of our discharge and our pay as civilians not beginning until our arrival in the Philippines. Anticipating these conditions, some of the men requested that they be ordered to the Philippines and discharged there, or that they be returned to the inactive list in the reserve corps, so that they could return to their homes with pay. Both of these requests were refused, and the men discharged along with the rest.

Several of us called on various Army officials in Washington and were told in every case that new legislation was necessary before we could be reimbursed. It is to acquaint you with these facts and to solicit your assistance in securing the necessary legislation that I am troubling you with this letter.

We all received a letter of appreciation from Major General Black in which we were heartily thanked for the way in which we had responded to our country's call, etc. A little consideration in the orders getting us into and out of the service would have been more to the point.

On May 1 a letter was addressed to the Secretary of War in which the above communication was quoted, with a request as follows:

Will you be good enough to inform Engineering Council through the undersigned whether the facts as related in the letter above quoted are interpreted by the War Department in the same way as by Mr. ——— and whether there is an official intention to present the facts to Congress for the purpose of securing authority to reimburse discharged engineer officers of the Army whose experiences were similar to that above related.

Up to May 24 no response had been received from the War Department, but we have hopes. While the author of the above letter recites an unfortunate train of circumstances, which seemingly reflects discredit on someone, judgment should for the time being be tempered with consideration. This war has been so big a thing that the mental capacity of man has been quite inadequate to direct everything rightly. An injustice has been done, but the correction in this case lies not in placing the blame but in securing reparation. Our Government is essentially just and the Congress will not advisedly do injury to any man. Let us have all the facts.

Bill Raises Salary of Director of Bureau of Public Roads

The agricultural appropriations bill, H.R. 3157, which was introduced in the House of Representatives May 26, 1919, provides a salary of $6000 per annum for the Director of the Bureau of Public Roads. The salary heretofore has been $4500. The total appropriations in the agricultural bill amount to $31,691,562. Among appropriations interesting to engineers, there may be mentioned those for the Forest Service, amounting to $5,966,869, of which $450,000 is for use in improving the roads, trails, bridges, fire lanes, telephone lines, cabins, fences, etc., in the national forests; for the Bureau of Chemistry, $1,381,571, and for the Bureau of Public Roads, $594,320.

$1,000,000 Trust Fund Bequeathed to Philadelphia

The will of Thomas Skelton Harrison, former American minister and consul general to Egypt, which was recently probated in Philadelphia, provides a trust fund of nearly $1,000,000 to be used in improving conditions in the municipal government of Philadelphia. It provides for a board of seven men to apply the fund to various municipal needs.

Army Engineer Board to Recommend System of National Roads

A board of Army officers has been appointed to consider a system of national highways in connection with the rural post roads system, for which appropriations were provided in the postoffice appropriation bill, passed Feb. 28, 1919. The board will be directed to prepare specific recommendations, to be submitted for the approval of the Secretary of War. The board will consist of Gen. E. E. Winslow, of the Corps of Engineers, and Maj. J. M. Ritchie, of the Motor Transport Corps.

Bureau of Mines To Dedicate New Pittsburgh Laboratories

The new million-dollar laboratories and workshops of the Bureau of Mines in Pittsburgh, Penn., will be dedicated Sept. 29-Oct. 1. The feature of the dedication will be a national "safety-first" meet, at which teams of miners from all over the country will compete for a cup and medals for rescue work and first aid to the injured. As there is great rivalry among teams of various mining companies it is expected that these contests will take at least two days. At the last national "safety-first" meet held in 1911 more than 18,000 miners were present. The contests are open to all teams from mining and metallurgical industries in the United States.

New Water-Supply for Phoenix

Plans for a gravity mountain water-supply for Phoenix, Ariz., provide for a 42-in. pipe line 157,500 ft. long from the Verde River, with an infiltration system at the upper end, and discharging into a reinforced-concrete covered reservoir of 25,000,000-gal. capacity. The cost of the project is estimated at $1,350,000. These plans have been prepared and submitted to the city commissioners by L. B. Hitchcock, city engineer, and Hiram Phillips, consulting engineer, St. Louis, Mo.

Salt Lake City Has $890,000 for Water-Works Improvement

In the bond issue of $2,000,000 recently approved at Salt Lake City, Utah, the sum of $890,000 is assigned for improvement of the water-supply and distribution system, and it is expected that contracts will be let and considerable work done during 1919. A gravity high-line supply conduit from Parley's Cañon will cost about $300,000; this will be of reinforced concrete and will be 26,000 ft. long, with a daily capacity of 34,000,000 gal. Feeder mains for this conduit, 10 to 24 in. in diameter, together with ordinary water-main extensions, will cost about $240,000. Other items include $200,000 for purchase or exchange of additional sources of supply; $100,000 for the conservation of City Creek by constructing one or more small reservoirs; $50,000 for developing various sources of local supply for serving the parks. S. Q. Cannon is city engineer.

Constructive and Progressive Aspects of New Branch of Engineering

National Conference on Town and Regional Planning, Industrial Cities, Zoning, Steam Railroads

That town planning is municipal engineering at its highest level, embracing and coördinating the many and various elements in municipal design, becomes more evident with each National Conference on City Planning. At the eleventh of these gatherings, held at Niagara Falls and Buffalo, May 26-28, most of the subjects discussed were in the domain of the engineer, and engineers made up a goodly percentage of those present.

That the city planners are dealing with practical matters and are making progress in their work the country over is shown by the main features of the latest conference. These included discussions and reports on planning industrial cities, zoning in cities of all classes, regional planning to meet the needs of groups of cities and their tributary areas, and the steam railroads as related to both industrial and regional planning. Besides these four subjects, civic centers and soldiers' monuments were considered.

Hereafter the conferences will be continued more nearly along the lines followed for the first eight years than was contemplated two years ago when the American City Planning Institute was tentatively formed. Conference members of a year's standing may become members of the institute, which will be devoted to research work, provided they have been for at least two years in charge of some city-planning work of a major character. This work is so defined as to include both landscape and building architects, engineers and lawyers engaged in city planning. Nelson P. Lewis, chief engineer of the Board of Estimate and Apportionment, New York City, was elected as president of the conference for 1919-20, and was reëlected as secretary of the conference.

President Olmsted's Address

Lessons drawn from his war experiences in planning cantonments and war-industry housing projects were the chief features of the address of F. L. Olmsted, who retired as president of the conference after serving 10 years. The difficulties encountered in securing coöperation in a complex undertaking, Mr. Olmsted said, are not so much due to the work in hand as to the mental and moral inertia that keeps different persons from getting together. The two chief dangers are (1) excessive departmentalization, under which each does his part sequentially and independently instead of in coöperation, and (2) some one man assuming that he knows it all and trying to make all his associates his subordinates.

Turning to another phase of his subject, Mr. Olmsted said that, so far as he remembered his experiences with the United States Housing Corporation, Philadelphia was the only city that had clearly distinct street plans showing what thoroughfares are needed beyond the district limits. Still another remark by Mr. Olmsted that will appeal to engineers was his statement that any proper city engineering organization should have a staff, if only a single man, engaged wholly in planning for the future needs of the city.

Commenting on Mr Olmsted's remarks, Arthur C. Comey, city planner, Cambridge, Mass., said that "however we may feel about it, municipal engineers are going to do a large part of town planning." This class of work will increase by force of the recent examples set by the Government, and there are not enough professional city planners to do it all. The city planning conference should bring in the municipal engineers.

Planning Problems of Industrial Cities

Growing attention is being given of late to the planning problems of industrial cities. These problems were outlined by John Nolen in a paper abstracted elsewhere in this issue, and they were specifically illustrated by wall plans from reports by Mr. Nolen on Niagara Falls, N. Y., Akron, Ohio, and Flint, Mich. Akron, Mr. Nolen said, has only one street extending clear through it unbroken, and that one is narrow.

Continuing this general subject and at the same time extending it into the field of one of the main topics, regional planning, Warren H. Manning, city planner, Boston, outlined a study he had made of the industrial-planning needs of Birmingham, Ala. The city has no up-and-down thoroughfares, only crossways. The adjacent villages, industrially related, should be connected with the city. Zoning is needed, and since the life of a building is 30 years, after which it becomes second-class, zoning for Birmingham is planned on the assumption that after 30 years the residence section on the lower level will become a manufacturing district, the houses going back to the higher levels.

As related to industrial planning, the rehousing operations of the Relief Commission of Halifax, N. S., were outlined by George A. Ross, of McDonald & Ross, Montreal, architects to the commission. Of 750 permanent new homes planned, some 200 are nearing completion. Although the devastated area was hilly, the original streets were laid out on the gridiron plan. Two diagonal streets have been provided to give better grades between the higher and lower levels. Street widths have been fixed to accord with grades, length and rise of streets. To give quick shelter, frame houses on a court-group plan were built. These will afford low-rent houses after their temporary occupants have moved. With a few variations in ground plan, 24 types of exteriors were secured for these group houses. A total of 110 individual houses has been built, and contract plans for 150 more are under way. Experience has shown that "hydrostone" or steam-cured hollow concrete blocks can be built for only 2.5% more than the cost of frame houses. The homes wrecked by the explosion two or three years ago were valued as of the date of the explosion. The relief fund bears the difference between their valuation and the actual cost of the new houses. In special cases, after careful investigation, aid is provided beyond that just mentioned. These statements apply to householders able and willing to acquire homes on mortgage.

The Steam Railroad and the City Plan

The relation of steam railways to the city plan was outlined by E. J. Fort, city manager of Niagara Falls, N. Y., and was also considered with special reference to that city by him and by Walter McCulloh, consulting engineer, Niagara Falls, and J. L. Harper, chief engineer of the Niagara Falls Power Co. Mr. Fort's paper is abstracted elsewhere in this issue. Mr. McCulloh reviewed four plans of railway relief prepared for Niagara Falls, those of the New York Central, the Grade Crossing Commission, John Nolen and E. P. Goodrich. Mr. Harper urged that in view of the great power developments of the future, resulting in a city extending to include Lockport, railway planning should cover more than the present small corner occupied by Niagara Falls.

The railroad problem was also discussed by J. E. Noulan Cauchon, engineer, Ottawa, Ont. As a matter of railway economics, Mr. Cauchon said, the railway problem is one of maximum tonnage on minimum grades, but the community requires safety and amenity as well. The speaker outlined railway relocations planned by him for Ottawa, Hamilton and London, Ont. These and the various plans for needed railway changes at Niagara Falls afford illustrations of one of the many city-planning activities of the day.

An Extension of City Planning

So important was regional planning considered by the framers of the conference program that an entire session was devoted to it. Papers were read by Thomas Adams on the general subject and by Morris Knowles on its more strictly engineering features. The paper by Mr. Adams is abstracted elsewhere in this issue. Regarding Mr. Adams' paper, it should be noted further that it included a detailed study of the Niagara Falls district on both sides of the international boundary, accompanied by maps and diagrams showing populations, resources and public utilities. Sewage-disposal prob-

lems of the region were discussed by T. W. Barraly, city engineer of Tonawanda, N. Y., who seemed to favor disposal through a combined sewage and power canal leading from Buffalo to Lake Ontario.

In general discussion, R. A. Pope, of New York City, said that regional planning is dependent on economic governing conditions and is therefore essentially within the province of the engineer. E. P. Goodrich, consulting engineer, New York City, said he was engaged in two regional studies that take into account the resources and export possibilities of the district.

Still another phase of regional planning, water fronts, came up at another session, when the Palisades Interstate Parkway of New York and New Jersey was described by W. A. Welch, chief engineer, and a proposed extension of the New York State Reservation at Niagara Falls so it would reach nearly the whole length of the United States side of the river—as does already the Dominion Reservation on the Canadian side—was outlined by Ansley Wilcox, of Buffalo. In this connection may be mentioned also a description of the proposed "peace bridge" across the Niagara River at Buafflo. A small appropriation for the study of this project was recently vetoed by Governor Smith of New York.

ZONING PROGRESS AND POLICIES

No subject evoked more interest, information and opinion than zoning. A supper session was devoted to brief reports on progress and an afternoon to residential zoning. Among the cities that have enacted zoning regulations are New York, St. Louis, Los Angeles, Oakland, Alameda, Berkeley and Palo Alto. Zoning for some cities has been authorized by the legislatures of New York, Pennsylvania and Nebraska, and by constitutional amendment in Massachusetts. Zoning regulations are being framed or are seriously proposed in Cambridge, Mass.; Buffalo, Cleveland, Detroit, Spokane, Portland, Ore.; San Francisco and other cities. A summary of the facts on zoning progress brought out at the conference may be obtained from Herbert S. Swann, 277 Broadway, New York City.

Archer C. Comey, of Cambridge, Mass., who opened the discussion on residential zoning, said that zoning as a whole is the largest single element in city planning. He thought that zoning regulations should be simple and drawn to last for 25 years. Zoning will stop four-fifths of the billboard nuisances in residential districts.

Charles H. Cheney, of San Francisco, held that regulations should be changed frequently to meet changing conditions. He urged that residence, business and industrial zones are necessary to insure reasonable rentals to wage earners. Unless land owners know that a given area will be restricted to residences they will insist on wide streets and heavy pavements suitable to business districts, thus increasing the price of lots beyond what low-priced dwellings can stand. The fundamental data for zoning are costly but necessary. They can be obtained in large part from the telephone companies, which are compelled to plan 20 years ahead. In establishing zones, neighborhood opinion should be secured, Mr. Cheney urged. This serves not only as a guide, but when brought out unmistakably is an argument that convinces the city councils that finally enact zoning ordinances. In Berkeley the Chamber of Commerce fixed the limits of the business district and the Manufacturers' Association set the bounds of the industrial zone. Harland Bartholomew, engineer of the St. Louis Planning Commission, said that zoning is a matter of four-fifths fact and one-fifth judgment. The facts should be put on paper, after which the plan can be worked out.

CIVIL CENTERS IN THEORY AND PRACTICE

A paper on the "Common Sense of the Civic Center," by Nelson P. Lewis, New York City, is abstracted in this issue. The group plan at Cleveland, on which more than $15,000,000 of obligations for land and buildings have been incurred, was described by Robert Hoffmann, city engineer. A county court house, a city hall and a Federal building have already been completed as parts of the group plan; a municipal hall is under construction and a public library has been planned and partly financed. Most of the large area of land for the mall has been acquired but not all of it has been cleared and, as the buildings thus far erected are scattered, the large outlay already incurred does not make a unit impression on either stranger or citizen. Perhaps, Mr. Hoffmann suggested, this was one reason why the voters recently agreed to a radical change in the plan for the location of the union station.

In a talk on "Soldiers' Monuments in Relation to the City Plan," by H. E. Jackson, of the Bureau of Education, Washington, D. C., it was urged that these express the spirit that animated the soldiers; also that it would be well to defer for some years, as have the French, attempts at works of art, since it is too early as yet to work out properly the ideals suitable for permanent war memorials of a purely artistic character. Speaking along other lines, Mr. Jackson pleaded for community or neighborhood organization and for social engineering. Four or five universities are considering courses for training social engineers, he said, and one has already decided to establish such a course.

Before adjournment the conference adopted resolutions urging the Bureau of the Census to adopt, for cities of 10,000 or more, the same districts or multiples of the same as were used in 1910; requesting the Secretary of Labor to urge mayors of all cities to appoint city-planning commissions; and asking the board of governors of the city planning conference to appoint a committee to study regional planning.

Finally, the city planning conference was notable for its large attendance and sustained interest through almost continuous sessions for two and a half days, for its social luncheons and dinners and, last but not least, for its undoubtedly favorable reaction upon both Niagara Falls and Buffalo, each of which is awakening to its great need for city planning. This reaction was especially notable in Niagara Falls, where the newspapers and some of the people are beginning to realize how little man has done for the convenience and amenities of a city for which nature has wrought on so grand a scale.

Dust Explosion in Grain Mill Causes Serious Damage

Nearly 50 persons were killed and about $3,000,000 worth of property was destroyed May 22 as a result of a dust explosion in the feed-grinding mill of the Douglas Corn Products Co., at Cedar Rapids, Iowa. A consequent fire caused much of the damage. Experts from the Department of Agriculture are making an investigation.

Dallas Engineers Get Together

The Dallas Chapter of the American Association of Engineers was installed May 25 by C. E. Drayer, national secretary. The meeting was attended by nonmembers, and resulted in the starting of a Dallas Engineers' Club, to include all engineers of that city. A committee is being formed, composed of representatives of all national societies, to study the situation and to report with recommendations. The suggestion for an all-inclusive local club was made by Jacob H. Brillhart, representative of the Texas Association of Members of the American Society of Civil Engineers.

Licensing was indorsed unanimously, and a committee was appointed to go over the bill drafted by the Texas Association of Members of the American Society of Civil Engineers. All engineers in the state will be enlisted to support the final bill.

Civic activity, publicity, legislation, compensation, national and local organization were discussed. The suggestion that there be an all-inclusive democratic national organization that could speak with authority on public questions and speak with a voice that would be heard was heartily applauded. The thought was expressed that such an organization should be parallel in form to our political government, so that proper contact could be developed for political activity.

Civil Service Examinations

California.—Civil engineer, grade IV, $2700 to $3900 per year; examination in Sacramento, San Francisco and Los Angeles as soon after June 14 as possible. File applications with State Civil Service Commission at Sacramento before June 14.

California. — Construction engineer (civil engineer, grade III), $2100 to

$2700 per year; examination in Sacramento, San Francisco and Los Angeles, June 20. File applications with State Civil Service Commission at Sacramento before June 14.

California.—Civil engineer, grade II, $1500 to $2100 per year; examination in Sacramento, San Francisco and Los Angeles, June 20. File applications with State Civil Service Commission at Sacramento before June 14.

California. — Senior engineering draftsman, grade II, $1500 to $2100 per year; examination in Sacramento, San Francisco and Los Angeles, June 20-21. File applications with State Civil Service Commission before June 14th.

New York.—Heating and ventilating engineer, office of state architect, $1500 to $2500 per year, June 28, apply to State Civil Service Commission at Albany for application forms before June 16.

United States

For United States civil service examinations, listed on the following page, apply to United States Civil Service Commission, Washington, D. C., or to any local office of the commission, for form 1312.

Senior engineer and senior architect, Interstate Commerce Commission, $1800-$2700 per year, June 10. File application before June 10.

Assistant designing engineer, Naval Ordnance Plant, South Charleston, W. Va., $9.20 per diem. July 8. File applications before July 8.

Valuation engineer, $3600-$4800 per year, and assistant valuation engineer, $2500-$3600 per year; technical staff, income-tax unit, Bureau of Internal Revenue, Treasury Department. No date specified.

Master computer, $2400 to $1800 per year, computer (Grade I) $1800 to $1400 and computer (Grade II) $1400 to $900, Ordnance Department. Applications will be received until further notice.

Calendar

Annual Meetings

AMERICAN WATER-WORKS ASSOCIATION; 47 State St., Troy, N. Y.; June 9-13, Buffalo, N. Y.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, 29 W. 39th St., New York; June 16-19, Detroit.

AMERICAN SOCIETY OF CIVIL ENGINEERS; 29 W. 39th St., New York; June 17-20, St. Paul-Minneapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS; University of Pennsylvania, Philadelphia; June 24-27, Atlantic City, N. J.

AMERICAN CONCRETE INSTITUTE; 6 Beacon St., Boston; June 27-28, Atlantic City, N. J.

Engineering Societies

The San Francisco Association of Members of the American Society of Civil Engineers made an inspection trip to the Mare Island Navy Yard May 24. About 60 members of the association made the trip, and were taken in automobiles to the various points of interest on the island, including the 150-ton floating crane, an electrically welded steel barge, the construction of battleships and destroyers, the operation of electric furnace, foundries, large machine shops, etc.

The Western Society of Engineers was addressed June 2 by Maj. Robert I. Randolph, 535th Engineers, Service Battalion, who spoke on his work in France in heavy railroad construction in the Toul sector. Capt. Paul Hansen, Sanitary Corps, U. S. A., who also served in the Toul sector, spoke on problems in connection with supplying the troops with water. On June 20 and 21 the society will celebrate its 50th anniversary. On the first day, engineering progress during the past 50 years will be the topic of discussion, and on the following day there will be a basket picnic at The Dunes.

The Engineers' Club of St. Louis held a joint meeting May 28 with the St. Louis Section of the American Institute of Electrical Engineers. The meeting was addressed by H. Weichsel, chief designing engineer, Wagner Electric Manufacturing Co., who spoke on "Insulation Resistance of Electrical Machinery," and by Prof. A. S. Langsdrof, dean of the schools of engineering and architecture, Washington University, on "Circulating Currents in Direct-Current Armatures and on Phase Relation in Interconnected Polyphase Systems."

The Technology Club of Syracuse, N. Y., held its annual meeting June 2. A dinner was given in honor of members who have returned from military service, each of whom spoke briefly of his experiences. The following officers were elected: President, Prof. Louis Mitchell; vice-president, Charles C. Trump; secretary, K. V. Farmer; treasurer, Marshall B. Palmer.

The Pittsburgh Chapter of the American Association of Engineers' banquet and ball, May 27, in honor of engineers returned from the Army and Navy, had Major Gen. William M. Black, Chief of Engineers, U. S. A., as the honor guest and principal speaker. About 200 guests were present. The Engineers' Society of Western Pennsylvania and and the Pittsburgh Association of Members of the American Society of Civil Engineers coöperated in the program.

The Civil Engineers' and Inspectors' Union, affiliated with the American Federation of Labor, was recently organized in Boston, with the following officers: President, Percival H. Mosher; vice-president, Frank McLaughlin; financial secretary, Leo S. Stone, 108 Waumbeck St., Roxbury; treasurer, William J. Cochran. The headquarters of the organization are at 3 Boylston Place, Boston.

The Southern California Association of Members of the American Society of Civil Engineers held a meeting and dinner May 14, at which the Hon. W. A. Johnstone, of the California State Water Commission, and the Hon. Jonathan S. Dodge, chairman of the Los Angeles County Board of Supervisors, were guests. Papers by F. H. Olmsted, Dr. Ford A. Carpenter and A. L. Sonderegger were read as a continuance of the symposium on flood control.

The Jackson, Mich., Engineering Society was addressed May 19 by W. L. Fox, of the Fox Machine Co., who spoke on the value of shop practice to draftsmen. A paper was read on "What the University of Michigan Extension Course Can Do for the Jackson Engineers."

The Oklahoma Chapter of the American Association of Engineers was installed June 2 by C. E. Drayer, secretary of the national organization. The officers of the chapter are: President, Fred L. Verity, and secretary, Erle K. Ramsey, office engineer, Oklahoma City.

The Society of Engineers of Topeka, Kan., held a regular meeting May 29, at which O. W. Griggs, valuation engineer, Santa Fé R.R., spoke on the subject of evaluation.

The Pennsylvania Railroad Section of the American Association of Engineers will hold its first annual meeting in Pittsburgh June 28. The headquarters of the section are at 1318 Fulton Bldg., Pittsburgh.

Personal Notes

MAJ. FRANK M. MASTERS, U. S. A., has received his discharge from the service and has opened offices for the practice of engineering at 204 Locust St., Harrisburg, Penn. Major Masters was inspecting manager, Philadelphia Ordnance District, and recently served as a member of the Philadelphia Claims Board.

LIEUT. F. H. DECHANT, U. S. N. R. F., formerly civil engineer, Bureau of Yards and Docks, Navy Department, at Quantico, Va., has obtained his release from active duty and is transferred to the inactive list. He has become associated with WILLIAM H. DECHANT & SONS, civil engineers, Baer Building, Reading, Penn.

M. J. SCAMMELL has resigned as assistant general manager of the Sparrows Point, Md., plant of the Bethlehem Steel Corporation. He has been connected with the plant since 1912, when he was appointed superintendent of

blast furnaces. In the reorganization in 1916, when the Bethlehem Corporation took the plant over, he became general superintendent of the steel mill and later was made assistant general manager of the plant.

FRED J. DEUTSCHMANN, Aurora, Ill., whose appointment as city engineer of Mitchell, S. D., was noted in *Engineering News-Record* of May 22, 1919, p. 1039, has not accepted the appointment, but will continue with the Wells Engineering Co., of Aurora, in charge of the construction of municipal and sanitary work.

CAPT. L. R. TILLOTSON, LIEUT. JAMES IRONS, and RAY A. FINNEY, all of whom have received their discharge from the 110th Engineers, U. S. A., have become associated in partnership under the firm name of the SHAWNEE COUNTY ENGINEERING CO., Topeka, Kan., and will specialize in highway engineering.

E. G. LANE, who was appointed chief engineer of the Baltimore & Ohio R.R., Lines West, in September, 1918, from the position of engineer maintenance of way, has been appointed with jurisdiction also over the maintenance-of-way department of the Baltimore & Ohio, Lines West, including the Dayton & Union R.R. and the Dayton Union R.R.

LIEUT. COL. GEORGE A. JOHNSON, Construction Division, U. S. A., and MAJ. WEBSTER L. BENHAM, Construction Division, U. S. A., have become associated in partnership under the firm name of JOHNSON & BENHAM, consulting engineers, with offices at 150 Nassau St., New York City, and the Pathfinder Building, Kansas City, Mo. Colonel Johnson, who is still in the service, but anticipates discharge in the autumn, was originally officer in charge of the water and sewer section in the Construction Division. He later became second in command of the maintenance and repair branch of the Construction Division. Major Benham received his discharge from the service May 1, having served as officer in charge of utilities and as construction quartermaster at Camp Funston, Kansas. He was later appointed regional supervising utilities officer for camps in the Southwest, and in March of this year was ordered to Washington as assistant to the chief of the Construction Division. The new firm will engage in general engineering practice.

CAPT. THOMAS GRIFFIN, Ordnance Department, U. S. A., who was recently discharged from the service, is now established at 2 Rector St., New York City, where he will engage in a general engineering business, specializing in the export of engineering supplies.

SEYMOUR CORLEY, 15th Engineers, U. S. A., recently discharged from the service, who was formerly connected with the Des Moines Bridge & Iron Co., has become superintendent of water-works and sewerage construction for Lawrence & McCann, general contractors, Eveleth, Minn.

CAPT. CHARLES DUBOIS, Construction Division, U. S. A., has received his discharge from the service and has become associated with the Bickle Co., engineers and contractors of Kansas City, Mo., and will specialize in highway construction.

C. E. BRASHEARS, formerly city engineer of Yakima, Wash., has been appointed inspecting engineer of the Yakima County sections of the Inland Empire Highway, which will be built this summer under the State Highway Department.

CAPT. LEWIS A. STEPHENSON, Ordnance Department, U. S. A., who was formerly stationed at Camp Funston, Kansas, has received his discharge from the service and has opened offices in Kansas City, Mo., for the practice of engineering.

G. CLYDE BALDWIN, engineer in charge of the United States Geological Survey office at Boise, Idaho, since 1911, has been transferred to Idaho Falls, in charge of the new office at that point.

CARL PAULSON, United States Geological Survey office, Atlanta, Ga., has been appointed engineer in charge of the office at Boise, Idaho, succeeding G. CLYDE BALDWIN, transferred to Idaho Falls, as noted above.

FRED CLECKNER has received his discharge from the service in the 309th Field Signal Battalion and has resumed his former work with GANNETT, SEELYE & FLEMING, engineers, Harrisburg and Erie, Penn.

DANIEL W. CHAMBERLAIN, assistant division engineer, California State Highway Commission, has been appointed assistant highway engineer for Fresno County.

E. C. CONNOR has been appointed chief engineer of public utilities of Dallas, Tex.

LEROY E. WOLFE, formerly of the Virginia State Highway Department, has become associated with the du Pont Co., Wilmington, Del.

W. B. SHORT, water department, City of Tacoma, Wash., has been appointed city engineer and manager of the water department of Bellingham, Wash.

A. R. SWEN, chief engineer, Iowa Railway & Light Co., Cedar Rapids, has resigned to become associated with H. R. GREEN, consulting engineer of Cedar Rapids.

J. B. CROLY has been appointed district manager, at Vancouver, B. C., in charge of the new office of the Dominion Engineering & Inspection Co., of Montreal.

B. H. MCCAMMENT and E. F. ERNEST, both of whom have received their discharge from the 110th Engineers, U. S. A., have become associated in partnership under the firm name of the FEDERAL ROAD ENGINEERING CO., Columbian Building, Topeka, Kansas.

LEONARD L. RYAN has been appointed manager of McCracken, Kansas.

OBITUARY

HENRY K. OWENS, consulting engineer, Seattle, died in that city, May 15, at the age of 61. He went to the Pacific coast in the employ of the engineering department of the Northern Pacific R.R. at the time of the completion of the line through to Seattle. He was afterward engaged in laying out the business district of the new City of Seattle after the fire in June, 1889. In recent years he had engaged in hydro-electric and irrigation development, including much work in the Columbia River district. At one time he was retained by the Northern Pacific as consulting engineer in the development of irrigation work in the settlement of reclaimed lands in Yakima Valley, Washington. He had made extensive studies in the possibilities of water-power and irrigation development in the Northwest.

PROF. ERNEST MARCEAU, president of the Polytechnic College, Laval University, Montreal, and chief engineer of canals, Province of Quebec, died at Sault au Recollet, Que., May 23, at the age of 60. He took his degree as civil engineer at Laval University in 1879 and joined the engineering department of the provincial Government. In 1894 he was appointed chief engineer of the Province of Quebec. For the past 10 years he served as president of the Polytechnic College.

FREDERICK T. CRANE, city engineer of Orange, N. J., for the past 25 years, died in that city, May 31, at the age of 65. For some years previous to his appointment as city engineer of Orange he had been engaged in railroad-engineering work. In 1916 he was nominated a member of the New Jersey State Department of Health.

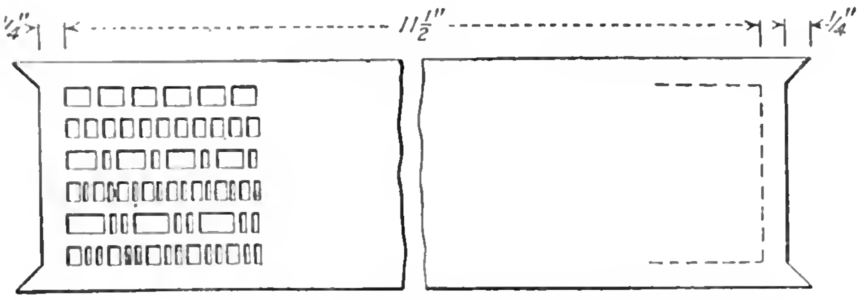
JOSEPH O. B. WEBSTER, for many years topographical engineer of New York City in charge of the laying out of streets, died in New York, May 30. He entered the service of the city in 1870 and for the past few years had been engaged in the engineering department of the Borough of Manhattan.

WILLIAM B. HOUGH, president of the Metal Building Materials Co., Chicago, died May 29. He was graduated from the Massachusetts Institute of Technology in 1900.

TIMOTHY M. RYAN, building contractor, of Seattle, died in that city, May 24. Mr. Ryan had been engaged in the contracting business during most of his 30 years' residence in Seattle.

Dot and Dash Lines Drafted by Simple Device

The drawing of uniform dot and dash lines may be accomplished by means of the simple ruling device shown in the accompanying illustration, which is formed by perforating very thin celluloid with rows of rectangles of varying widths. To manufacture the instrument celluloid of 1/100-in. thickness is used. This is punched with the desired spacings and then rolled into a bow shape.



CELLULOID DOT AND DASH RULING DEVICE

The method of use is to place the celluloid over the drawing where a dotted or dot-and-dash line is desired, with the concave side of the bow downward. A straight-edge is then placed over the particular row of spacing desired, and a right-line pen is drawn over the celluloid touching the paper at the perforations. Upon removing the straight-edge, the spring in the instrument throws it upward from the paper. This prevents blotting.

The instrument is about to be placed on the market by the Defiance Manufacturing Co., of New York, which is the sole licensee under the patents.

Grand Central Palace, New York, to Become a World Trade Mart

Upon the return of the Grand Central Palace, of New York City, to the Merchants' and Manufacturers' Exchange, it is proposed to develop the building as a center for the extension of American commerce in foreign countries, as well as for the importation of foreign goods into America. The building, which is 12 stories high, was taken over by the Government for a base hospital, and is now being vacated.

Industries will be grouped and permanent exhibits placed on the eight upper floors. The four lower floors will be utilized for the annual expositions which have made the building famous heretofore.

Some of the permanent exhibits that will be installed in the near future include farm implements and tractors, hardware and home furnishings, mining machinery, railway equipment, textiles and printing machinery.

It is believed that such a building will be of great service to foreign buyers in expediting the selection of goods, and to domestic dealers and jobbers in selling. The office of the Merchants' and Manufacturers' Exchange is at 405 Lexington Ave., New York.

Union Meeting of Manufacturers of Handling Equipment

The Material Handling Machinery Manufacturers' Association, 35 W. 39th St., New York City, announces a coalition meeting of all manufacturers of mechanical handling equipment in the United States. The meeting will be held at the Hotel Astor, New York City, June 11, 1919. The invitation is extended to all manufacturers of cranes, winches and hoists; elevators; gravity and power-conveying machinery and apparatus; industrial trucks, tractors and trailers; bulk-handling machinery, and all makers of equipment and accessories such as storage batteries, bearings, rope for hoists, buckets, electric controllers and apparatus, etc. The advertising managers of the various companies are invited to hold a preliminary meeting at the Hotel Astor on Tuesday evening, June 10.

An interesting program has been prepared, at which speakers of national reputation will talk on the various aspects of coöperative advertising and promotion. A general "forum" discussion will be conducted in the afternoon. Further particulars can be obtained from Zenas W. Carter, secretary of the association promoting the meeting.

Business Notes

THE NEW YORK TESTING LABORATORIES, mining, metallurgical and chemical engineers, announce that they have opened new offices and laboratories in New York City, at 74-80 Washington St. In addition to its other work, this organization will specialize in inspection of materials at the source, and will act as consultants in smelting, foundry, drop-forging and heat-treating practices and in investigation of metallurgical shop troubles.

THE H. K. FERGUSON CO., Cleveland, Ohio, announces the appointment of Lieut. E. D. Stearns as sales manager. Before entering military service Lieutenant Stearns was a member of the Fort Pitt Engineering Co., of Pittsburgh.

THE EQUIPMENT CORPORATION OF AMERICA, Lumber Exchange Building, Chicago, Ill., announces the following changes in its organization: H. Grant Leonard, assisted by J. L. Shields, will be district manager of the Pittsburgh office, which has been moved to quarters in the Empire Bldg. Alfred Reynolds, formerly field salesman in the Chicago district, has been made Chicago district manager. The Philadelphia district branch office, in the Land Title Bldg., has increased its capacity.

THE SILENT HOIST CO. announces the removal of its New York office to 487 Broadway.

THE FERGUSON INDUSTRIAL CO. has been incorporated to transact a general contracting business, with main offices in the Spitzer Building, Toledo, Ohio. J. E. Ferguson is president and treasurer and P. H. Dexheimer is vice-president and field manager of the company.

THE MURRAY IRON WORKS CO., Burlington, Iowa, announces that F. C. Orrell has resigned as manager of the Minneapolis office of the Allis-Chalmers Manufacturing Co. of Milwaukee, to assume charge of the Chicago office of the Murray Iron Works Company.

THE ACME BLUE PRINT PAPER CO., 115 S. Dearborn St., Chicago, announces its entrance into the field as manufacturer and dealer in drawing materials, sensitized papers and blueprinting.

Trade Publications

The following companies have issued trade publications:

THE CLARK TRUCTRACTOR CO., 80 E. Jackson Boulevard, Chicago, Ill.; folder, 6¼ x 9¼ in., four pages, illustrated; describes a light three-wheel machine of 1½-ton capacity for industrial work; it can be used as a tractor or fitted with a box or dump body for carrying material.

THE S. G. H. RUBBER-STONE CO., Detroit, Mich.; booklet, 6 x 9 in., 19 pages., illustrated; subject, "The Modern Roadway," as built of "Rubber-Stone."

THE REDWOOD MANUFACTURERS' CO., Hobart Building, San Francisco, Cal.; catalog, 6¼ x 9¼ in., 115 pages, illustrated; describes the construction and installation of "Remco" Redwood pipe, and gives technical data in tabular form, covering such information as that necessary in proportioning water-power installations, capacity of pipe at various heads and with various diameters of pipes, discharge in gallons per minute and hour with velocity in feet per second, velocity head in feet and loss of head in feet per 1000 ft. of length, for sizes of pipe from 2 in. up to 144 in. in diameter.

THE STORMS MANUFACTURING CO., Crawfordsville, Ind.; folder, 3¾ x 9¼ in., 18 pages, illustrated; describes one-man collapsible steel forms for small and large concrete culverts for roads.

May Contracts Aggregate $100,000,000

Bids Wanted Now on 200 Projects—General Advance in Lumber—Prices at Several Centers

By Alden W. Welch

In bemoaning the slackness of the construction season it must not be overlooked that contracts let in May, alone, aggregated $100,000,000 and in number exceeded 1200. Furthermore, on May 29 bids were wanted on 203 projects. These projects will soon materialize as contracts awarded, in which event more than a thousand contractors will have plenty of new work for their organizations.

The need for construction in every field is so acute that the situation cannot be called satisfactory until all contractors are busy. The improvements in the past two months, however, are notable. The 655 contracts awarded in March aggregated $48,000,000, about half the record for May. The table shows the increase participated in by every department of construction. So noteworthy is the acceleration that no one branch can be singled out for particular commendation. Specially gratifying, however, is the activity in public works, as shown for sewers, bridges, roads and dredging.

Better Demand for Steel

The demand for steel has improved. The failure of the Railroad Administration to break the price of rails has created a better sentiment in the industry. It is believed that the 200,000 tons reluctantly placed will be followed by further business from the railways. Other important orders were placed by automobile manufacturers, one being for 300,000 tons of billets, sheets, wires and tubes. Lower ocean freight rates have stimulated exports. As showing that the price is being maintained to Pittsburgh levels in England, a recent sale of billets was at $63, including ocean freight at $20. British billets are $67.28.

The most important price change since last month is in lumber, the rise being nation-wide. The high mark occurs in St. Paul, where 1-in. fir jumped $7 per 1000 ft. b.m. In the statement of conditions in the various centers of the country, which follows, the lumber situation is detailed. Lumber prices have not fluctuated in Chicago or St. Louis, and only slightly in New York, but Baltimore, Kansas City, Los Angeles, San Francisco and Seattle deserve attention.

Baltimore—The downward tendency in cost of building materials continues slight but steady, with its most noticeable effect in the cement and steel markets. Plain structural steel is being sold on the jobbing basis at $54 a ton, f.o.b. Baltimore, or $2.70 per 100 lb., with bar sizes and shapes under 3-in. at 10c. less; fabricated steel is being offered at prices varying according to whether light or heavy, but averaging $90 to $95 a ton; for floor-beams and columns $90 to $100 a ton is asked. These are decided drops over April. Cement, sold a month ago at $3.45 per barrel in more than 5-bbl. lots, can now be had at $3.10 a barrel.

The lumber market, apparently, is experiencing the most fluctuation, prices for the various grades rising and falling, on small margins, in sensitive touch with the law of supply and demand. At this writing lumber (common) is bringing $42 to $46 per 1000, delivered from local yards in city; heavier timber, up to $54, delivered. Common brick, sand and gravel prices have not changed since last month.

St. Paul—Recent bids show decreases in the following commodities: $3\frac{1}{2}$-in. creosoted wood block, from $2.20 to $2.13 (St. Paul specifications); natural Austin cement, $1.55 to $1.45; brick paving block, $37.50 to $36.50. There is a slight increase all along in lumber, the most notable being a jump of $7 in 1-in. rough fir, and $4 in 8 x 8-in. pine.

Kansas City, Mo.—Crushed stone has advanced from $1.70 and $1.80 for $1\frac{1}{2}$- and $\frac{3}{4}$-in., respectively, to $1.90 and $2; common brick, from $14 to $15; yellow pine, 1 in., rough, 10 in. and under, 16 ft. and under, has jumped $2.75 per 1000, and yellow pine, 2-in. t. and g., dressed and matched, same sizes, has advanced $1.50. These advances are due to an active "Build Now" campaign. The *Star* of Sunday, May 25, contained 60 want ads for carpenters, several for from 25 to 60 men.

Lumber Stocks Oversold

Many of the Southern and Western lumber mills have withdrawn from the market because they have oversold their stocks to a point where it will require the accumulation of the next 30 to 60 days to cover present orders. The present ocean rate of lumber of $51.75 per 1000, as against a pre-war rate of $9, is causing foreign private concerns to hold back on orders now.

Lumber firms controlling large Southern mill interests say that if the rate drops as expected—to about $40 by Sept. 1—lumber will go to the highest bidder, and it is expected that the European demand will be so great that an abnormal advance at home will follow. Stocks of all kinds of lumber in the hands of manufacturers today are said to be the lowest in history. Foreign governments, which are demanding lumber of all grades and sizes, are glad to get it at the present market price, despite almost prohibitive freights.

Public work has been retarded in the past few weeks by unfavorable weather conditions. It is improving, however. Many very large contracts, especially sewers, one for $1,500,000 and another for $2,500,000; also a diking project of $1,000,000 will be ready for letting by the city in the near future.

San Francisco—The rise in lumber prices is said to be due to increased demand. Mill owners claim they were not making sufficient profit, so they advanced their prices as soon as the demand warranted. The new prices are published in the section following this article.

Los Angeles—With a steady increase in the volume of building and engineering operations, and with the prospect of a labor shortage, no reduction in the price of construction materials is looked for in Los Angeles. Lumber prices have advanced about $4. Prices of other materials, with the exception of a few like explosives, rope, etc., remain steady. These exceptions show reductions in price, due, no doubt, to the creation of a surplus through the cessation of hostilities. Building construction, street and highway work, irrigation, drainage and sewer installation and hydro-electric development are all back practically to a pre-war stride.

Seattle—Between Apr. 23 and May 23 the price of lumber, wholesale, carload lots, to dealers, f.o.b. Seattle, best grade only, advanced from $17.50 to $20.50. This increase is attributed to steady demand from all parts of the United States and the growing number of orders from Europe. There is a decided shortage of stocks. Mill stocks are practically depleted and production is below normal. Official figures show orders are about 10% above normal, production about 10% below normal, and shipments about normal.

Contract prices for recent work have averaged 10 to 15% below those of last year. Conditions generally seem to be more stable and contractors are showing much more interest in bidding.

ANALYSIS OF CONTRACTS LET IN MARCH AND MAY, 1919

Water-works	Sewers	Bridges	Streets and Roads	Excavating and Dredging	Industrial Works	Non-Industrial Buildings	Federal Government	Miscellaneous	
24	75	7	302	6	115	75	37	40	Number let in March

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING AND CONTRACTING

E. J. MEHREN *Editor* CHARLES WHITING BAKER *Consulting Editor*

Volume 82 NEW YORK, THURSDAY, JUNE 12, 1919 Number 24

Factory Methods in Pile Casting

CIVIL engineering construction rarely lends itself to factory methods or to the utilization of the economies of multiple production of small units, but there are cases where such methods can be applied, where machinery supplants hand labor to an extent far beyond the common practice, and where there are consequent marked economies. One such instance is the pile-casting yard at the Norfolk Army base, described on another page, and another is the similar yard at the Boston Army base, which, though not here described, has many of the details of the Norfolk yard. Pile production at these yards made remarkable and regular progress, corresponding in every way to the best factory work. The application of machinery and proper routing played a large part in the results secured.

Deceiving the Draftsmen

IN THE May issue of the *Monad*, Robert W. Shelmire calls attention to the pernicious character of the advertising of certain schools for draftsmen which quote such extravagant promises as "from $35 to $100 per week to start," following a short course in mechanics or drafting. He points out that of 13 advertisements of similar tenor in *Popular Mechanics*, 10 give Chicago addresses, and calls upon the engineers of the American Association of Engineers to investigate these schools and compel them either to tell the truth or, through the force of public opinion, go out of business. We earnestly hope that action will follow Mr. Shelmire's appeal. With draftsmen generally dissatisfied, and properly so, with their compensation, matters should not be made worse by bringing new men into the ranks with promises that are not likely to be fulfilled.

Concordant Tests Wanted

CONCRETE proportioning is the livest issue today in the field of concrete. For the time the questions of cement specification and stress determination—two of the old controversies—are dormant, but the work of Edwards and Abrams reported last year has started a train of confirmatory investigation which is just now reaching publicity. Only a part of the current discussion of the subject is given in this issue; more will follow in this journal in the next few weeks, and there is little doubt that the Testing Materials and Concrete Institute conventions the last week in June will bring together in discussion several of the more important investigators. Until the time when all the current evidence shall be in, it would be futile to attempt any summary of the facts as they have been presented. It is worth while now, however, to note the dissonance of the laboratory tests as presented in the article in this issue, and to suggest to the American Society for Testing Materials and the American Concrete Institute that here is a fertile field for controlled duplication of tests in many laboratories. Until a program of experiments, laid out by some central body and conducted in many responsible laboratories, develops some concordant results, the proponents of the various theories or methods can hardly wonder that the man in the field still sticks to his old 1 : 2 : 4 mix.

Seeing Themselves as Others See Them

CONTENTED for decades with the unsurpassed scenic grandeur of its cataract, and more than content with its money-making possibilities, first from its tourist traffic and later from hydro-electric power, Niagara Falls is only now awakening to the fact that as a municipality it has done nothing to make itself attractive to either its visitors or its citizens. To a few of its people vision has come recently, resulting in some attention to city-planning needs. The City Planning Conference held at Niagara Falls May 26-29, 1919, brought home to many residents of that city for the first time how ugly the man-made part of the city is to the visitor who gets away from the river front or who views the American side of the upper part of the gorge from the Canadian side. Never before in the automobile tour of inspection that prefaces the city-planning conferences have the visitors to a conference city had so depressing a trip as the one on May 26 through the residential, business and industrial districts of Niagara Falls. This was evident to residents of the city who attended the conference sessions, and the local press advertised rather than hid the fact. It is to be hoped that seeing themselves as others see them will give impetus to the city-planning movement at Niagara Falls.

Shipbuilding at Its Climax

WITH the month of May, American Shipbuilding reached the climax of its achievement. Through the great enterprise of the Emergency Fleet Corporation, the industry was magnified ten or twenty times within the past two years. For many months its producing capacity has been in process of development, until it has now reached peak production. A total of 768,025 dead-weight tons was completed and delivered, the main part of this tonnage composed of 87 large steel vessels, averaging over 6700 dead-weight tons carrying capacity. This performance represents an increase of nearly half over the April output. Yet even the present production does not represent the full power of the remarkable shipbuilding machine which the country created, for there has been a steady contraction in operations since last November. Wood shipbuilding has been discontinued, and in the steel and concrete yards cancellation of contracts and enforcement of normal-

time schedules have slowed up the pace. At maximum output, it may fairly be concluded, a monthly production well exceeding 1,000,000 dead-weight tons might be attained with the facilities now in existence within the borders of the United States. Launchings during May lagged behind completions, apparently for the first time since our war shipbuilding began; yet with 706,000 tons launched during the month and keels laid for 596,000 tons, it may be anticipated that the May deliveries may be surpassed by a small margin for a month or two to come. In effect, however, the program is now on the decrease. Future stagnation of our great shipbuilding industry can be prevented only by foreign orders: while no relief in this direction has yet come, there are grounds for optimistic feeling. Sound conditions of demand exist, as is evidenced by some recent sales of vessels on the part of the Shipping Board in which no less than $210 per dead-weight ton was obtained. Shipbuilding for private account may therefore be expected to be fairly active after the Fleet Corporation's orders are executed. For many years, however, the production record which today is a reality will stand as an unapproachable record.

Some Shipbuilding Cost Figures

CHAIRMAN Hurley of the Shipping Board has just given out the first figures on the cost of shipbuilding under the Emergency Fleet Corporation's program. For the total of 2434 vessels, aggregating 13,885,106 dead-weight tons, $206 per dead-weight ton will have been paid when all is over. This figure includes nothing for shipyard plant extension or housing and the like, items that are separately accounted for. But while $206 is actually paid out by the Government, it is partly offset by certain important tax payments. Income and excess profit taxes have been paid by shipbuilders in amounts ranging up to $40 per dead-weight ton, and Chairman Hurley estimates that the average payment has mounted to $25 per ton. Large additional tax payments have been made by the industries that furnished materials for the ships—wood, steel, engines, and equipment—but the amounts are not readily ascertainable. It is evident, then, that the net cost of the ships to the Government has been less than $180 per dead-weight ton, by no means an extravagant figure on the general scale of the times. The actual cost to the shipbuilder, of course, is considerably lower, and this cost is the figure by which the competitive capacity of the industry will be determined.

Standardization Referred to Societies

WITH the Engineering Standards Committee's action in deciding upon complete reorganization, some difficult problems are placed before the councils of the five founder societies, whose approval or disapproval is required. As approval will mean assuming an obligation to finance the work, particular point is given to the situation, for in these times engineering societies find it necessary to inquire rather carefully whether a proposed expenditure will give commensurate return. In the case in hand the uncertainties and problems are largely chargeable to the unfortunate fact that the committee has failed to define, or even roughly describe, what the term "engineering standards" shall cover. This was a remarkable omission at the time of original organization: it is even more remarkable now. It invested the committee from the start with vagueness of purpose and function, and the impression made was not improved through the committee's failure to make contact with the profession at large. Now, with the broadening into an "association," a much enlarged body in which technical and commercial organizations of all kinds may hold membership and the founder societies will play a subordinate part, this same vagueness is intensified, to the extent of inspiring doubt as to the engineering control and even as to the technical status of the association's future activities.

The officials of the committee have decided to withhold the details of the proposed reorganization from public knowledge until the founder societies have had an opportunity to act. It may be assumed, however, that the general scheme sketched by Dr. E. B. Rosa in *Engineering News-Record* of May 1 and May 8, 1919, is to be followed, though perhaps on a reduced scale. The motive leading to reorganization was to extend the scope of the committee's work to cover the preparation of industrial safety codes, such as rules for the construction of elevators, ladders or machine guards—something rather widely different from specifications for materials, standards for machine screws, or sizes of hydrant threads.

In these circumstances three important questions present themselves: What field of work will the association occupy? Is this field now taken care of in reasonably satisfactory manner? Will the association improve the results now being achieved, or will it injure or destroy existing institutions? These questions, concerning which the committee itself has hitherto maintained silence, are at the core of the difficulties referred to. As we suggested in our issues of Apr. 10 and Apr. 17, the issue is the sound continuance of most important work now being carried on, and perhaps even the survival of societies now flourishing.

Will Large Contracting Organizations Take Up Highway Work?

OF LATE there has been much urging of large contracting organizations to engage in highway work. The large future confronting the highway field has been pointed out, as well as the opportunity to secure sizable contracts worthy of the resources and skill of large organizations.

From the standpoint of the public there can be no doubt that it is desirable to let contracts for long stretches, provided capable contracting organizations having sufficient resources to buy adequate plants can be induced to take up the work.

But how does the large contracting organization regard the highway field?

To answer that question one of the editors of *Engineering News-Record* has sought the opinion of the officers of some large construction companies which have heretofore engaged in other work than highways but which are now contemplating entering the highway construction field. Their views, as summarized by Mr. Hill, will be found on p. 1150 of this issue. The story merits the most careful consideration of highway engineers.

In many of the charges which Mr. Hill sets down, as the temporary spokesman for these large contracting companies, will be recognized faults frequently alleged

against those who employ contractors, whether public officials or small private owners. Great as has grown the volume of construction work in recent years (until the war came) there has been no conspicuous change in the relationship between contractor and owner on the general run of small and average-size public-works jobs. There the contractor is still mistrusted and is not accorded the standing given to any other business man. Obviously, there are some things that cannot be fully defined in the specifications, and for the interpretation of these clauses the contractor is in the hands of the engineer. That is to be expected, but the insertion of meticulous clauses which at the sole judgment of the engineer, or of a subordinate under him, may be used to the disadvantage of a contractor is not conducive to that kind of relationship which should exist in a contract supposed to be mutual. These clauses can be offset only by a reputation for fair treatment, and such a reputation, the contractors believe, has not been established.

That the just causes for complaint must be removed needs no long demonstration. For a time the large contracting organization will be glad to take any work to keep busy, but just as soon as there is opportunity to pick and choose—in other words, when the volume of construction approaches that of the pre-war period—the large, competent, financially strong construction organization will select work in which the relationship not merely leads to profit but rests on the conviction of the owner that the contractor for a fair price will do a thoroughly good piece of work.

If the big contracting organization by the time the pre-war demand is approximated has not found the assurance that it will find in the highway field fair compensation and fair treatment in return for honest work, it will employ its resources elsewhere and the great opportunity which now lies before engineers to secure the services of these competent organizations for the benefit of the public will have disappeared.

We recognize, and so does Mr. Hill, that legal requirements are responsible for some of the undesirable features in public-works contracts. But, as Mr. Hill well says, the facts alone are important.

The Growth of the Draftsmen's Unions

FROM various parts of the country come reports of the rapid growth of draftsmen's unions. The international federation states that it has 5000 members in 25 locals, and that the Chicago branch alone has 700 members. In certain of the municipal departments in New York a majority of the draftsmen have joined, while in San Francisco not only have most of the draftsmen entered the union but 85 per cent. of the assistant engineers in municipal service as well.

While at first thought such growth is surprising, it is evident on reflection that it is but another manifestation of the dissatisfaction with compensation that has been with us for the past eight or ten years. That dissatisfaction has, of course, increased very materially on account of the price changes during the war.

To understand what is happening, however, one needs but to recall that six years ago a committee was appointed by the American Society of Civil Engineers to study the subject. That was evidence of dissatisfaction, and a groping after a remedy. Later came the American Association of Engineers with a welfare program that included the matter of compensation, and its rapid growth has certainly been due in part to its emphasis on this question. Now another agency comes forward, and, pointing to its effectiveness in other lines, offers its aid in the effort to get higher compensation.

Nor are the unions and the American Association of Engineers alone in making efforts in this direction. Engineering Council appeared before the railroad wage board and at the present time has at work a committee on compensation and classification of engineers. Its three subcommittees—on Federal, railway and on state and municipal employment—are actively at work making their classifications and getting the necessary data on which to build the proposed minimum salary grades.

The procedures, whether of Engineering Council or of the unions, rest on the theory that engineers must resort to collective bargaining in order to get higher pay. That theory was not accepted, or at least not advanced, by the civil engineers' reports in 1914 and 1917.

Therefore, the organizations at the extremes—the national technical societies (functioning through Engineering Council) on the one hand and the unions on the other—are at one in their theory. The divergence is one of method. The more conservative members of the profession are fearful of the use of "union methods," including the strike, or threat of strike. Those who seek quick results, however, wonder whether effective action can be counted on from the national societies, or their representative, Engineering Council. Right here the two wings join issue.

We have no doubt that the lowliest draftsman, ineligible to membership in the national technical bodies, would much prefer to see the results come through the action of the societies than through the union. He is interested in results chiefly, of course, but is not blind to the prestige which would accrue to all engaged in engineering work if the profession took care of its own. The strike, moreover, does not appeal to men of the type engaged in engineering work, and we should expect considerable defection if a strike were called.

What weapons, then, remain for getting results? There are at least two—the force of public opinion and the mediation of Government agencies. Upon these, both Engineering Council and the American Association of Engineers are relying. They can be made effective agencies, without doubt, but their effectiveness requires well-directed publicity, with a full and strong showing of fact.

What the outcome of present efforts will be remains to be seen. Shall we recede, now that we have advanced so far as accepting the theory of collective action on compensation? In England, as the Webb report on professional organization showed (*Engineering News-Record*, Apr. 10, 1919 p. 712), collective action on compensation is a confirmed part of the procedure of professional societies. Despite what has happened in England, however, it is hard to predict that we shall adopt the method permanently. The draftsmen will retain it, but will the professional engineering bodies? Likewise, it is impossible to tell what will happen as the result of another year or two of effort to secure higher remuneration. The effectiveness of the various procedures will be closely watched, and also the manner of the doing.

Meanwhile, it is important that all should know what efforts are under way, and particularly that those who desire action but are not in sympathy with the idea of getting it through the unions should realize that other bodies have the matter actively in hand.

Tests of Two Recent Theories for Proportioning Concrete

Fineness-Modulus and Surface-Aggregate Methods, Both of Which Depend on Water-Cement Ratio, Do Not Seem to Insure the Necessary Workability of Mix

By G. M. Williams and Watson Davis

Associate Engineer and Assistant Engineer, Respectively, United States Bureau of Standards, Washington, D. C.

The following tests, made at the United States Bureau of Standards, controvert the fundamental principles of two theories for proportioning concrete which are receiving current attention. Following the article will be found a reply by Prof. D. A. Abrams, the propounder of one of the theories. A reply from Captain Edwards, the advocate of the other theory, will appear in an early issue—Editor.

During the past year two new theories for the proportioning of concrete mixtures have been proposed. One, fully described by Prof. D. A. Abrams in Lewis Institute Bulletin No. 1, "Design of Concrete Mixtures" (see *Engineering News-Record* of Apr. 17, 1919, p. 758), is based upon tests which seem to show that the strength of concrete depends only upon one factor, the ratio of mixing water to cement. The second, proposed by L. N. Edwards of Toronto and presented at the 1918 convention of the American Society for Testing Materials (see *Engineering News-Record* of Aug. 15, 1918, p. 317), bases the quantity of cement upon the surface area of the aggregate and includes a formula for quantity of mixing water to produce concretes having equal plasticity and equal strength. Studies now under way in the Bureau of Standards indicate that neither of these two methods insures what is most necessary in practical concrete work—that is, a proper "flowability" or workability. Some of the results of these tests are given here in proof of this assertion.

The above Bulletin No. 1 states that for a given plastic condition of the concrete and the same mix there is an intimate relation between the fineness modulus of the aggregate and the strength and other properties of the concrete. The grading of the aggregate may vary over a wide range without producing any effect on concrete strength, so long as the cement-water ratio remains unchanged. Referring to the sieve-analysis curves, it is said that any other analysis curve which will give the same total area below the curve corresponds to the same fineness modulus, and will require the same quantity of water to produce a mix of the same plasticity, and gives concrete of the same strength, so long as it is not too coarse for the quantity of cement used. In other words, for given concrete materials the strength depends upon one factor only—the ratio of water to cement.

The "surface-area" method of proportioning assumes as its basic principle that the physical properties are primarily dependent upon the relation of the volume of cementing material to the surface areas of the aggregate.

It is stated that the strengths of mortars are dependent upon the quantity of cement in relation to the surface areas of the aggregates, and the consistency of the mix. Also, that strengths of mortars of uniform consistency containing sand aggregates of varying granular combinations are directly proportional to the quantity of cement they contain in relation to the surface area of the aggregate. It was found that "normal," uniform-consistency mortars of varying cement content and of varying sand gradings were produced when the quantity of water used in the mix was made equal to that required to reduce the cement to a normal-consistency paste, plus an amount equal to the surface area of the sand in square inches divided by 210, i.e.,

$$\text{(1) Water (cc.)} = \left(\begin{array}{c}\text{Weight of cement } (C) \times \\ \text{Percentage required to produce} \\ \text{"normal"-consistency paste}\end{array}\right) \frac{\text{Total surface area of sand (sq. in.)}}{210}.$$

As shown above, the water-cement ratio method, in final result, is not concerned with details of proportioning the cement or grading of the aggregate, but, regardless of the reason for varying the water content, the water ratio dictates once for all the concrete strength.

TABLE I. PHYSICAL CHARACTERISTICS OF AGGREGATES

* Surface areas for aggregates 1.. 9, 40, 264...280 are computed under the assumption that the surface areas of particles passing the 100 mesh sieve are the same as the areas of those retained for unit weight, as was done by Mr. Edwards.

The "surface-area" method requires the selection first of some ratio of cement to surface area of aggregate, such as 1 g. cement to 10, 15, 20, or 25, etc., sq.in. of area. With this ratio fixed and with the quantity of mixing water determined by the above formula, mortars of the same plasticity and of the same strength are said to result.

It is important to note here that *the "surface-area" method after fixing a ratio of cement to surface area of aggregate arrives at the same final conclusion as does the method proposed by Professor Abrams—that strength depends only upon the ratio of mixing water to cement.* The proof of this statement is as follows: Let

C = Weight of cement in grams.

p = Percentage of water for normal consistency of the cement.

A = Total surface area of aggregate in square inches.

$N = A/C$ = square inches of surface area of aggregate per gram of cement. Arbitrarily selected before test.

w = c.c. mixing water.
c = volume of cement in cubic centimeters.
As given previously

$$w = pC + \frac{A}{210} \qquad (1)$$

From above $A = NC$ (2)
Substituting (2) in (1)

$$\frac{w}{C} = p + \frac{N}{210} \qquad (3)$$

in which p and N are constants. To express the weight of cement in the form of volume

$$\frac{w}{0.67c} = p + \frac{N}{210} =$$

constant, which is the water-cement ratio proposed by Professor Abrams for equal strength, or

$$\frac{w}{c} = K$$

It appears from the foregoing that with w/c constant, Professor Abrams should obtain constant strength values in every case, while Mr. Edwards by his theory should obtain constant strength values if the cement content is proportional to the surface area of the aggregate, or if the mixtures be made up by the usual volume method of proportioning, the strengths should vary inversely as the surface area per unit volume of aggregate. In support of the first theory it is shown in Table II of Lewis Institute Bulletin No. 1 that the strengths of 27 concretes made with the same ratio of water to cement are essentially the same, whereas the surface areas of the aggregates per gram of cement varied from 5.6 to 31.3. If the first theory is correct, it would seem that the surface area of the aggregate has little apparent influence on strength, while if the second is correct, varying strengths should have been obtained for the concretes included in the above table.

Relation of Flowability of Concrete to Tests

The fundamental requirement in the process of concreting is plasticity, flowability, workability or whatever that property may be called which makes a concrete placeable with a reasonable amount of work. It is essential that this factor receive proper consideration in the laboratory. For the same flowability an aggregate containing much fine material will require a greater amount of water than one which carries little fine. The judgment of the operator cannot be depended upon to insure concretes of equal flowability when the proportions of cement to aggregate or gradation of the aggregate in the same proportions varies widely, as must often be the case. The adoption of the "slump test" or the "cylinder pull off," as applied to the freshly mixed concrete, was a great step forward in the control of this important factor, but we have found that the cylinder slump test is of value only over rather small ranges of consistencies. It often gives misleading results when used near the limits of these ranges when comparing lean and rich proportions, and also for proportions leaner than 1 : 1 : 2, depending somewhat upon the gradation of the aggregate.

In most of the tests, descriptions of which follow, consistency determinations have been made, both with the cylinder and with what seems to be a more logical and satisfactory means of determining the flowability; that is, with the vibrating steel plate. The plate is supported at its center and on the center of the plate a fixed quantity of concrete is molded in a cylindrical

form whose height is one-half its diameter, the form is removed and the edge of the plate is struck a fixed number of measured downward blows. The increase in diameter of the concrete expressed in per cent. is designated as relative flowability.

The conditions of the tests were as follows:

Cement—A standard brand of portland cement has been used throughout the series of tests shown.

Storage—All specimens were stored in damp closet or in water, as indicated. A relative humidity of between 90 and 95% was constantly maintained in the damp closet.

Testing—All compression tests were made on standard testing machines of 20,000- and 100,000-lb. capacities. The 6 x 12-in. cylinders were capped one end before testing and the other end was ground to a plane surface. The 3 x 6-in. cylinders were capped top and bottom with neat cement paste at the time of molding and the ends were ground plane just previous to the test.

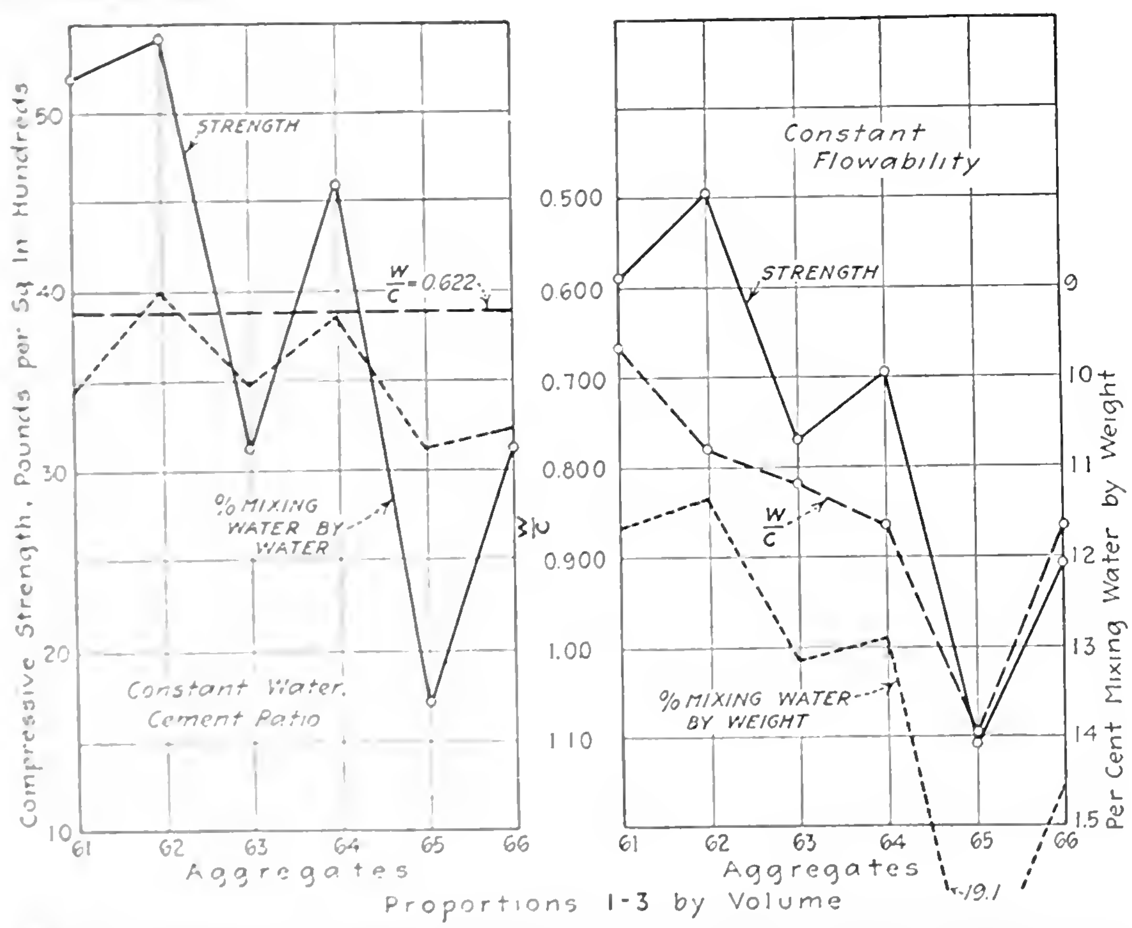

FIG. 2. STRENGTH TESTS OF MORTARS OF WIDELY VARYING GRANULAR COMBINATIONS (SEE TABLE III)

Aggregates—The aggregate, sand and gravel, from the Potomac River, used generally in all classes of concrete construction in the vicinity of Washington, was screened into its various sizes, using screens of the Tyler standard screen scale.

Proportions—All proportions, unless indicated otherwise, are by volume, reduced to weight measure for accuracy.

Method of Mixing—All concrete for 3 x 6-in. cylinders was mixed by hand in large, sheet-metal pans. All specimens in any one series were molded the same day by the same operator. Concrete for 6 x 12-in. specimens was mixed in a batch mixer.

Tests of the Proposed Methods

In Table I are shown the granular analyses and other physical properties of the aggregates included in the tables following.

In Table II (graphically in Fig. 1) are shown the results of tests made by combining constant weights of cement and mixing water with varying percentages of standard Ottawa sand, and of gravel passing the ¾-in. and retained on the ⅜-in. screen. These mixtures are much richer than most mortars ordinarily used in practice, but were made to show the effect of addition of very different aggregates with a constant water-cement ratio. The quantities of aggregate are varied from 0 to 2 parts by weight of the cement. With increase of added aggregate it is seen that density (that is, the ratio of volume of solids, cement and aggregate, to a unit volume of concrete) increases while strength decreases. It is also seen that the mixtures containing standard sand are stronger than those containing the coarser gravel. In general, it was found that flowability was reduced more by the addition of the coarse aggregate than the fine. This was indicated equally well by the slump test and the vibrating plate, and was noticeable to the eye at the time the specimens were molded. Had sufficient mixing water been used in every case to give the same flowability as was obtained for the neat cement, still greater reductions in strength would have resulted.

Attention is also directed to the relation between surface area and strength. In every case the surface areas of the standard sand mixtures are 16 times as large as for the gravel mixtures of the same proportions, and the strengths are considerably higher.

It is usual to conceive of concrete as being made

† Judged by eye and flow when heaped and shaken, checked by cylinder slump test; probably not so exact as later flowability determinations.

up of an aggregate glued together with cement paste. In view of the results shown in Table II it would seem to be more accurate to consider a concrete as being made up of a relatively small quantity of neat cement paste separated and diffused throughout the mass of a large volume of inert adulterant, which results in economy at the expense of strength.

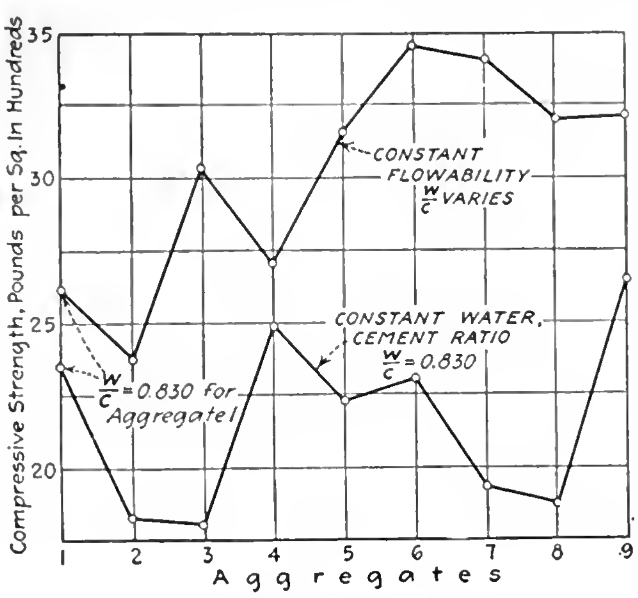

FIG. 3. CONCRETES WITH AGGREGATES OF SAME FINENESS MODULUS
Showing the variation in compressive strength with constant water-cement ratio and also the same aggregates with flowability constant. (See Table IV.)

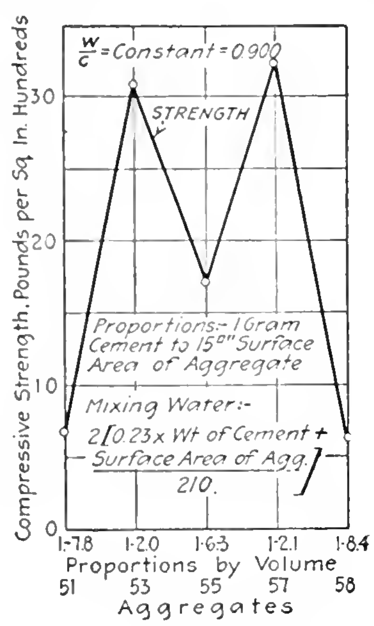

FIG. 4. STRENGTH OF MORTARS PROPORTIONED BY THE SURFACE AGGREGATE METHOD
(See Table V)

In Table III (graphically in Fig. 2) are shown results of tests made by combining one part cement to three parts of aggregates of widely varying granular composition. In one case the water-cement ratio was kept constant, and in the second group the water content was varied to give mixtures having constant flowability. The main points to be noted in this series of tests may be stated as follows: There appears to be little relation between surface area of the aggregate and compressive strength, and with constant water-cement ratio, compressive strength is not constant but varies greatly for the different aggregates when combined in the proportion of one part cement to three parts aggregate.

In the tests shown in Table IV (graphically in Fig. 3) all aggregates have the same fineness modulus, 5.40, with the exception of No. 9, which has 5.26 for its modulus. One part of cement was combined in every case with three parts of aggregate by volume. In one set the water-cement ratio was maintained constant ($w/c = 0.830$) and in the second the quantity of mixing water was varied to give constant flowability. With w/c constant, the flowabilities were found to vary more than is indicated by the results given by the slump test. This was apparent under the trowel and to the eye at the time the test pieces were molded, and was later confirmed when the series was duplicated with flowability constant.

It is seen that with w/c constant there was not only considerable variation in flowability but also a marked difference in compressive strength. Aggregates Nos. 3, 5, 6, 7 and 8 showed large increases in compressive strength when w/c was varied to give equal flowability as compared with No. 1, which was used as the base.

Increase in mixing water generally results in lower strength, but the magnitude of the change in strength varies for each aggregate.

Briefly, there is no apparent relation between surface area of aggregate and strength; also flowabilities and strength were not found constant for a constant w/c.

The series of tests shown in Table V (Fig. 4) was planned to meet requirements of the surface-area method of proportioning. As noted in the table, the actual proportions varied from 1 : 2.0 to 1 : 8.4 by volume, due to the use of 1 g. of cement for every 15 sq.in. of surface area. As for the aggregates shown in the preceding tables, the surface-area calculation is based on the assumption that the particles are spheres and

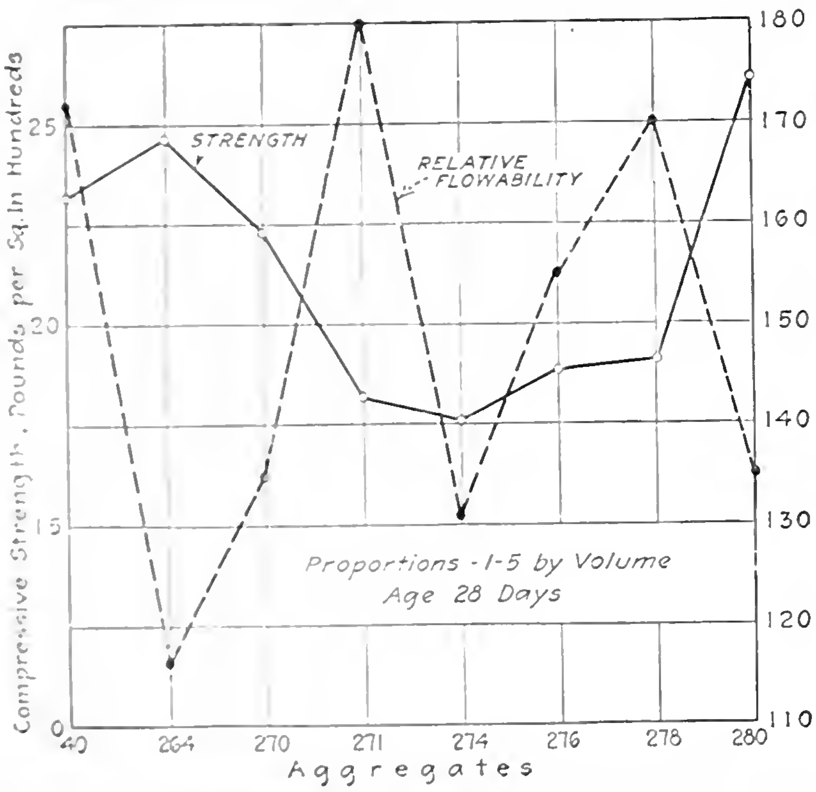

FIG. 5. CONCRETES MADE WITH AGGREGATES HAVING THE SAME FINENESS MODULUS

Showing variation in compressive strength and flowability with constant water-cement ratio (See Table VI)

that their average diameter is the mean of the openings in the sieve passed through, and retained on. Values obtained are only approximate, but are probably proportional to the true areas, which it is impossible to determine.

The formula proposed for determining the quantity of mixing water furnishes far too small an amount of water to produce a workable mix for all aggregates. In these tests the quantity was doubled, and those aggregates having small surface areas were too dry, and those with large surface areas entirely too wet.

Water Formula Is Inadequate

The inadequacy of the water formula is shown by comparing the amount which it would specify for a 1 : 3 standard sand mortar with the quantity which is ordinarily used in the laboratory.

Percentage for normal consistency = 24.

Surface area standard Ottawa sand = 400 sq.in. per 100 grams.

Assume batch of 500 grams cement and 1500 grams sand.

By "surface-area" water formula

$$\text{Water} = 0.24 \times 500 + \frac{6000}{210} = 148.6 \text{ cc. or } 7.42$$

per cent.

The United States Government specification for portland cement specifies 10.5% of mixing water for a cement having a normal consistency of 24. Water = 10.5 × 2000 = 210 cubic centimeters.

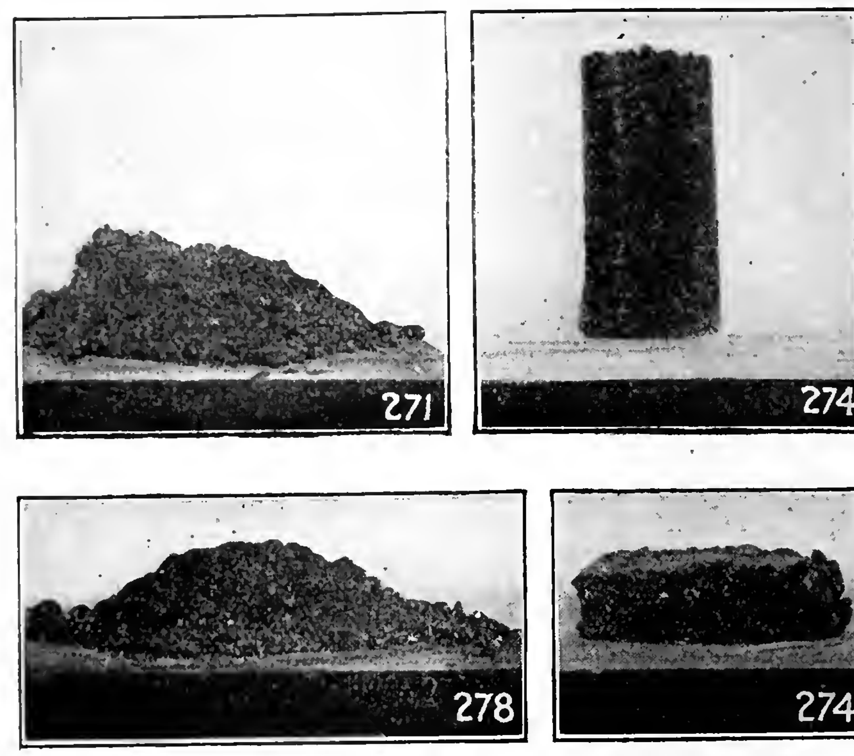

FIG. 6. RESULTS OF SLUMP AND FLOWABILITY TESTS OF THREE AGGREGATES. NOTED IN TABLE VI

Upper views show conditions after completing the cylinder slump tests; lower two views show specimens after the flowability tests

The "surface-area" normal-consistency mortar would therefore contain 61.4 less grams of water for a batch of 2000 grams.

It was foreseen that strict adherence to this formula was impracticable, and all calculated water quantities were therefore multiplied by 2, resulting in a constant water-cement ratio of 0.900. A very large proportion of the advantage which should have been obtained in the rich mixtures was thrown away by the excessive quantity of mixing water. It is an admitted fact that the granular composition of an aggregate is reflected by the amount of water required to produce a concrete of the same flowability, but, as shown previously, since the water-cement ratio is constant, no consideration is given to variation in the amount of surface area. The formula is equivalent to one which bases the water required on cement content only.

In view of these tests and the variation in water required for different proportions, or for aggregates varying widely in granular composition in the same proportion, it is difficult to see how by any chance a 1 : 2 could be compared with a 1 : 8 combination as to strength, as stated in Lewis Institute Bulletin No. 1, if proper consideration is given to flowability, or even if *w/c* is kept constant. Here the widest possible range in flowability between the 1 : 2 and 1 : 8 proportions was observed with *w/c* constant. Modifying the mixtures to obtain equal flowabilities would have resulted in much greater differences in strengths than those obtained.

The tests included in Table VI (Fig. 5) are duplications of the concretes shown in Table 2, Bulletin No. 1, Lewis Institute, so far as duplication can be made in another laboratory. A part of this Table 2 is shown in parentheses. Instead of Elgin, Ill., aggregate, the local

Potomac River sand and gravel were used. The material was separated by screening on the various sieves and then recombined in the percentages shown in this table so as to have the same fineness modulus of 6.04.

Using cement from the same lot with eight of these aggregates numbered in Table VII to correspond with the numbers in Lewis Institute Table 2, batches of one part cement to five parts of aggregate were mixed in a batch mixer with the quantity of water specified by the formula for a 1: 5 proportion, modulus 6.04, and molded into 6 x 12-in. cylinders. The 1.10% consistency was used, giving the same ratio for all aggregates with a value for *w/c* of 0.898. Five 6 x 12-in. cylinders were tested at the 28-day period with the results shown in Table VI.

The slight difference shown for square inches of surface area per gram of cement, between the figures given in the accompanying Table VI and Table 2 in Lewis Institute Bulletin No. 1, are probably due to our regarding the surface area of aggregate passing the 100-mesh sieve as equal to that of the particles retained, as was done by Mr. Edwards in his report.

The results shown for the slump test and the flowability test indicate the wide variation in flowability. After the slump test was made with aggregates 264 and 280 and no slump was found, the masses of concrete were picked up by hand and carried back to the mixer without losing their shape. Aggregates 40 and 271 were of a consistency suitable for reinforced-concrete construction. Aggregate 278 resulted in what would be termed a harsh-working concrete, apparently being too dry as measured by the cylinder slump test, but showing very good flowing qualities as indicated by the flowability test.

In Fig. 6 are photographs of the cylinder slump test on batches made with aggregates 271 and 274, respectively, showing the marked difference in consistency as shown by this test. There are also photographs of the vibrating plate test for flowability on concretes made with aggregates 278 and 274. The difference in the spread caused by the vibration of the plate can be plainly seen.

The results of Table VI fully confirm the results obtained for constant water-cement ratio as shown in Table IV both as to differences in flowabilities and strengths. The results also confirm the statement in Lewis Institute Bulletin No. 1 that there appears to be no direct relation between the surface area of the aggregate and the compressive strength of the concrete.

The tests here reported indicate that the discrepancy noted between our results and the results obtained by Professor Abrams and Mr. Edwards is due fundamentally to wide differences in the consistencies, or flowabilities, of the concrete mixtures. While we have found large variations in the strengths of different concretes in which the water-cement ratio is maintained constant, this is of secondary importance in view of the fact that the concretes as made were not of comparable consistencies.

In view of the potent influence of a small amount of mixing water on the strength of concrete, the proper testing of concrete in the laboratory requires that the desired consistency, or workability, or plasticity, or flowability (all here meaning the same thing) shall be definitely arrived at. The need for an apparatus capable of measuring this property with considerable accuracy now seems apparent, and we believe the development of such an apparatus is worthy of the concentrated effort of all who are engaged in the study and testing of concrete.

Conclusion

In the field "flowability" is a fundamental requirement in order that economy in construction and good workmanship may result. Increased flowability may be obtained by the use of more mixing water alone, or by the use of more cement or fine aggregate, which, in turn, will require an even larger quantity of water. Since flowability is obtained by the use of more water, which in turn tends to lower compressive strength, it is of the greatest importance that concretes as tested in the laboratory have the same flowabilities, otherwise they are not comparable. On any work there is some minimum condition of flowability which must be obtained, and an endeavor should be made to attain this same condition in the laboratory so far as possible.

That this same condition of flowability cannot be obtained if the water-cement ratio is to be kept constant is the basic criticism which we have to offer to the two theories under discussion. If *w/c* is kept constant, even for a given ratio of cement to aggregate, then the condition of equal flowability must be disregarded.

If, as we believe, flowability is a fundamental consideration, then *w/c* is only an incidental relation, which is the resultant of the more important factors, cement, aggregate, and flowability, and, in itself, is of no direct value to the engineer in proportioning concrete materials. The *w/c* relation considers only water and cement. From the results of the foregoing tests it is apparent that (1) flowability, (2) cement, and (3) aggregate are the three important factors to be considered in the proportioning of concrete mixtures. The proper flowability is essential for the economical handling and placing of the material; it is desirable to reduce the quantity of cement to a minimum for economy; and the choice of aggregate is usually limited, but can often be improved somewhat in quality at slight expense. Water, while an essential, is dependent entirely upon the above three factors.

Any method of proportioning concrete which can be generally applied must therefore take these variable factors into consideration, and, whatever the brand or quantity of cement, whatever the type, physical condition, or quantity of aggregate, flowability of the concrete must be considered, first and last, as of fundamental importance.

Aggregates Too Coarse in Bureau of Standards Tests

Most of the Aggregates Are of Unusual Gradings Which Were Advised Against in Use of Fineness-Modulus Method

By Duff A. Abrams

Professor in Charge of the Structural Materials Research Laboratory, Lewis Institute, Chicago

IN THE following discussion of the tests by Messrs. Williams and Davis, little will be said with reference to the surface-area method of dealing with concrete mixtures proposed by Captain Edwards. My views on this subject, together with new test data, are to be presented in a later communication to *Engineering News-Record*. This discussion will refer only to such por-

tions of the Bureau of Standards report which deal with the water-ratio fineness modulus method of designing concrete mixtures which was developed in this laboratory.

The authors state that "studies now under way in the Bureau of Standards indicate that neither of these two methods insures what is most necessary in practical concrete work; that is, a proper flowability or workability." I do not see that there is any necessary relation between these methods and the flowability of the concrete. Any desired degree of flowability can be secured by methods which are well known to every practical concrete man: that is, by using more water, richer mixtures, different grading of aggregates, other methods of handling, or some combinations of these factors. What we have attempted to do is to bring out the basic principles of concrete mixtures in a way that would eliminate "rule-of-thumb" methods of dealing with materials and proportions, and to enable the engineer to "design" a concrete mixture and estimate the influence of given changes in the composition of the concrete.

It is true that the method proposed by Captain Edwards can be reduced to the relation between the water-ratio and the strength of concrete. However, there is a very important difference between the surface-area method and our own in that, according to my views, Captain Edwards' method does not give the proper quantity of water as between mixtures of different makeup. The algebraic proof given by the authors establishes nothing more than what Captain Edwards originally assumed; namely, that the strength of the concrete is constant for a constant surface area of aggregate, so long as the quantity of cement and water are based on surface area. It will be pointed out in my discussion of Captain Edwards' report that the uniform strength obtained in his sand-mortar tests was due to the fact that a constant water-ratio was used.

The importance of workability, or flowability, as the authors have termed it, has been fully realized and pointed out in all of the reports emanating from this laboratory. I agree that the slump test which we have used is not ideal, but I fail to see how the vibrating-plate method can be any improvement. It is different; but there must be numerous difficulties in the way of standardizing such a determination, and it would not lend itself to the requirements of field use as readily as the slump test on 6 x 12-in. cylinders. The authors have used the 3 x 6-in. cylinder in making most of their slump tests. It would not be expected, from our experience, that this size of cylinder would give dependable results. Apparently, the slump values are from a single determination. Not fewer than five tests should be used for this purpose when endeavoring to establish principles.

Tables Discussed in Detail

A brief discussion will be given of the tests in each of the tables. It is notable that in most of the tables the mixtures and gradings of aggregates are quite unusual and do not at all represent the type of concrete with which the engineer has to deal. It will be shown that in these tests the authors have disregarded two essential considerations pointed out repeatedly in our Bulletin No. 1, "Design of Concrete Mixtures," as follows: (1) The grading of the aggregate should not be too coarse for the quantity of cement used; (2) the concrete must be plastic. These requirements are mentioned by the Bureau of Standards' engineers, but they were entirely overlooked in planning the tests and making the specimens.

There is a great diversity in the form and size of test pieces used, consequently it is impossible to make any cross-comparisons, but each table must be studied separately. The results are, in general, the average of two or three specimens made from a single batch. In Table VI, five specimens were made. Our experience has shown that this method will not give concordant results. Practically all of our experimental work is based on the results of from 5 to 10 cylinders, each made from a separate batch on different days. Two to 5 specimens *from a single batch* are little more dependable than a single specimen. It is the *batches* that vary more than the specimens in a batch. This emphasizes the necessity of mixing as many batches as possible. In many instances the specimens used were of small size—probably too small to give good results with the size of aggregate used.

The concretes in Table II were of a freakish nature in four respects: (1) Very rich mixtures were used; (2) the aggregates were of sizes that are never used in concrete; (3) in the leaner mixtures the grading of the aggregate was too coarse for the quantity of cement; (4) the last two mixtures were too dry for proper workability. The coarsest gradings which are permissible with a given quantity of cement are given in Table 3 and Fig. 5 of our Bulletin No. 1. It is there shown that for a 1:2 mix with aggregate graded up to $\frac{3}{4}$ in. the highest permissible fineness modulus is 5.90, whereas the authors use 7.00. The water-ratio for the two leaner mixtures in this table is about 70% of that required in accordance with our water formula. If we eliminate the last two tests in this table, we find that the remaining four results of the standard sand mortars gave a mean variation from the average of 4.4 and 5.1% at 7 and 28 days, respectively. The corresponding values for the $\frac{3}{4}$-in. gravel are about 12 and 16%. The standard sand tests are as uniform as would be expected from the number of specimens made and the extremely rich mixtures used. However, the two groups of tests are not consistent in themselves. It is not clear why the gravel tests should give results entirely different from the standard sand tests, unless it can be attributed to the large size of the aggregate used in the 3 x 6-in. cylinders, or to some other variation in method.

In Table III we find again that the principles of using plastic mixtures and avoiding too coarse aggregates for the quantity of cement used have been entirely disregarded. All but the first test in the "constant water ratio" group are too dry, as shown in Table A herewith.

TABLE A. TESTS WITH CONSTANT WATER RATIO IN TABLE III OF WILLIAMS AND DAVIS PAPER

Aggregate No.	Fineness Modulus Used	Fineness Modulus Allowed	Water Ratio Used	Water Ratio Required	Remarks
61	6.00	4.70	0.62	0.60	Much too coarse
62	4.60	4.70	0.62	0.69	Little dry
63	3.20	3.10	0.62	0.79	Little too coarse; too dry
64	4.00	4.30	0.62	0.73	Dry
65	2.00	1.85	0.62	0.94	Little coarse; very dry
66	4.00	2.50	0.62	0.73	Much too coarse; too dry

The fineness modulus "allowed" is taken from our Bulletin No. 1. The water-ratio required was calculated from the water formula used in our tests. Only *one mixture* (62) out of the entire group of six can be considered normal concrete, and even in this instance the grading of the aggregate is freakish.

It will be noted that the water-ratios used under the "constant-flowability" tests show almost a constant increase over the quantities given by our water formula, which verifies the results of our slump tests. Since all of the mixes in this group are plastic, we would expect the strength to be reflected by the water-ratio, had it not been that four of the aggregate gradings were too coarse. The remaining two tests (62 and 64) show a satisfactory agreement between the water-ratio and strength. All of the aggregates in Table III were of a grading which would be termed "freakish." In No. 61 there is no material finer than the No. 8 sieve; in 62, 63 and 64 there is no material finer than the 48 sieve. In 65 a uniform size of aggregate is used, and in 66 practically all of the material is between the 14 and 28 sieves. These features are in addition to the consideration of being too coarse for the quantity of cement used. The conclusions of the authors based on these tests are entirely erroneous, since they failed to take into account the obvious limitations in the composition of the concrete.

In Table IV we find that two aggregate gradings are decidedly too coarse for the quantity of cement used, and six of the remainder are so near the border line that slight variations in manipulation of the concrete might make them too coarse. Aggregates 7 and 8 are decidedly freakish in that all material below the 48- or 28-mesh sieve is omitted. This may account for the low strengths, although in general such a result would not be expected from these gradings. If we consider the strengths secured from aggregates 1, 4, 5, 6 and 9, (which are the only ones approaching normal concrete mixtures) it will be found that the variation in strength is less than 5%, whereas in the same table the variation of two tests using the same aggregate (1) and same water-ratio is 10%. In other words, the tests which the authors have offered as proving the incorrectness of the water-ratio theory give only one-half the variation found in duplicate tests in the same group. Aggregate 4 gives practically duplicate tests which vary 8%. It will be noted also that the tests given for "constant flowability" show a greater variation in slump than do the tests under "constant water-ratio."

The tests reported in Table V are the average of two or three 2-in. cubes. In this group we find that concretes from aggregates 51, 55 and 58 are too coarse for the quantity of cement used, and too dry. The fineness-modulus value used throughout is 4.55, whereas our Bulletin No. 1 points out that the maximum value which may be used with the grading and mixture used with aggregate 51 gives a fineness modulus of 3.50; for aggregate 55, 3.10 and for aggregate 58, 3.60. In other words, there are only two tests out of the group that can be considered as giving usable strength results; both of these are approximately 1: 2 mix. These two mixes having the same water-ratio give uniform strength, in spite of the wide variation in grading of the aggregate, as would be expected. The conclusions of the authors, based on these tests, are obviously erroneous.

Laboratory Variation Inexplicable

I am unable to offer an explanation for the strengths found by the authors in their Table VI, in which they have duplicated eight of the gradings used in Table 2 of our bulletin. Our tests gave uniform strengths, whereas the tests made by the Bureau of Standards are quite variable. It is possible the explanation may be found in the method of mixing the concrete. While the details of the mixing are not given, it seems probable that a batch of about 1 cu.ft. was mixed in a machine having a capacity of 5 or 6 cu.ft. Considerable experience in our own laboratory has indicated that single batches of machine-mixed concrete are likely to be erratic. This would be especially true of fractional batches which were probably used in this case. [The Bureau of Standards tests in Table VI were made from concrete taken from a full machine batch. The smaller specimens in their other tables were hand-mixed.—Editor.] It should be pointed out that the gradings used in our tests were somewhat too coarse. Subsequent experiments led us to recommend the use of 5.80 fineness modulus for the size of aggregate and mix used in this group. A slight variation in the methods of manipulation might throw these mixtures into the region where they would be too coarse.

The authors have misunderstood the statement in our Bulletin No. 1 concerning the comparison between 1: 9 and 1: 2 mix so far as strength is concerned. My purpose in making this comparison was to bring out the fact that the strength of the concrete has no necessary relation to the quantity of cement used. Our tests did not give uniform workability; on the other hand, the workability was very different. Nor was the aggregate of the same size or grading. The tests did, however, bring out emphatically the essential dependence of strength on the water-ratio, which is quite contrary to the statements found in most of the textbooks, to the effect that the strength of the concrete is proportional to the amount of cement used.

It will be of interest to study the mixtures used with reference to the gradings of aggregates and consistency of concrete. Table B herewith gives the result of such a study.

TABLE B. COMPARISON OF MIXTURES IN TABLES II TO V, WILLIAMS AND DAVIS PAPER

Table	Number of Mixes Falling in Each Group: In Table	Too Coarse	Too Dry	Too Coarse and too Dry	Freak: Mix	Freak: Grading
II	12	4	4	4	8	12
III	12	8	5	3	? (1-3)	12
IV	18	4	0	0	? (1-3)	6
V	5	3	3	3	......	4
Total	47	19	12	10	......	34

The tests in Table VI are omitted from this discussion, since the aggregates were duplicates of certain gradings used in our tests. Over 40% of the aggregates were too coarse for the quantity of cement used; 26% of the mixes were too dry; 21% were both too coarse and too dry; 72% of the aggregates were of "freakish" grading.

Freak mixtures and gradings should not give results essentially at variance with fundamental principles. There is no reason to expect that mixes which are much too dry for plasticity will follow definite laws. Such tests should not be cited as establishing the errors of principles which are based on thousands of tests of concretes of normal composition. It has been pointed out that in the majority of instances the grading of the aggregate was too coarse for the quantity of cement used, and in a large number of instances the mixtures were too dry. In some instances concrete suffered from both of these ailments. In view of the shortcomings mentioned above, the tests reported by the Bureau of Standards cannot be interpreted as a serious criticism of the methods of design of concrete mixtures developed by this laboratory.

Large Construction Companies Shun Road Work

Politics, Narrow Business Practices and Petty Contract Restrictions Are Objectionable to Construction Managers of Large Affairs

By C. S. Hill
Associate Editor, "Engineering News-Record"

Roadbuilding is now the largest single task before the construction industry of the United States. Unless the leaders of this industry as well as the rank and file of contractors who have for the most part, and also most capably, performed the lesser tasks of preceding road programs, shall array themselves with Federal, state and community officials to advance this task, its accomplishment will be retarded. How large construction organizations regard road construction as an opportunity for employment is, therefore, a question of vital importance. The answer, as it appears after careful inquiry and conferences with directors of such organizations, is presented in the article and discussion which follow—Editor.

To EXPEDITE the enormous program of construction which confronts them, public road officials need to enlist the services of large construction organizations—those organizations which heretofore have perceived nothing that offered profitable occupation of their resources in the small isolated-contract method of doing road work. A favorable conjunction of circumstances has placed these contractors for a time at the call of road officials. Large hydraulic developments and heavy railway, bridge and foundation work have been stopped. Until they start again, contractors who have looked to them for employment will turn to road work. It depends upon the acumen of road officials whether they continue in road work. Candidly, the likelihood that they will is not too promising.

Large contracting organizations cannot be permanently interested in road construction, unless they can be assured contracts of sufficient magnitude to command their full resources, and unless they be accorded the broadminded consideration in road work to which they have been accustomed in work for private corporations. With these inducements lacking, those large contractors who have for the moment exhibited an interest in road construction will withdraw to their old lines of enterprise as soon as bridge, railway, foundation work and kindred kinds of heavy construction resume their pre-war activity.

Character of Business Relationship

The importance of large-mileage road contracts has been fully emphasized in *Engineering News-Record* of Mar. 13, 1919, p. 503, and of Apr. 24, 1919, p. 831. Little has been done anywhere, however, toward defining the new conditions which must be created in business relationship between contractors and highway officials. Diplomacy and, perhaps, to some extent, delicacy, have kept contractors from speaking frankly. We propose to do so here, but first it is desirable to understand the character of the business relationship between the large construction companies and their private-works clients.

Contractors who have grown great through successful construction for private industries are considered and treated by those interests as experts in construction and as men of affairs. The master-and-servant relationship has disappeared, and in its place has grown something akin to the relationship of partners in a mutual enterprise. A certain flexibility is a tacitly recognized factor of any formal agreement into which owner and contractor enter. Cognizance is given by both to possibilities which may readily arise and which may change the complexion of an agreement, and both stand prepared to concede modifications in prices and requirements where they are demanded by fair dealing and mutual justice. Honesty of intention is conceded by both parties to the agreement, and meticulous prescriptions to prevent either from overreaching the other are largely discarded.

These statements do not picture an imaginary relationship; it exists in its fullest measure between many well known contractors and their clients. All unusually successful contractors enjoy this relationship in great measure. That they do, and that the advantage is real, is evidenced by the fact that these contractors will generally bid lower on private than they will on public work.

Large Organizations Not Attracted

Stress is laid on this relationship between the large construction organization and its private-works clients, because it has an important bearing on the task of enlisting the service of these organizations in the road-construction industry. They are not greatly attracted by the opportunity as they appraise it. Some of the reasons, as given by contractors, can be briefed as follows:

Road construction has brought too many hardships upon contracting in the past few years. It has been directed with too little active sympathy with the contractor's difficulties.

Too great willingness has been shown to take advantage, at the expense of the contractor, of a rising price and wage market.

The practice of calling for bids merely to try out the market, with no intention of awarding contracts, is too common.

There is too common neglect to state them when limiting prices will rule.

Too great stress has been laid upon possibilities of dishonesty.

Bludgeon clauses are too many in road specifications.

Low prices often overshadow contracting experience and financial ability.

Too many road departments have attained a reputation for "breaking" contractors.

All of these accusations can be proved by example. There are too many to permit full elaboration of each, but it is worth while to consider a few and show how the large contracting organization, whose entry into road construction is being considered, is reacting to their influence.

Bludgeon clauses are perhaps no more common in road specifications than they are in the specifications for other pubic works, but they are frequent. That such a meaning of these clauses is intended will be denied. Consider, however, this clause: "Portions of the pavement showing voids in the concrete after finishing and removal of the side forms shall be rejected." Beyond

doubt the engineers who wrote this clause intend a fair and reasonable judgment on porous spots in the pavement edge. What, however, was the practical effect of the clause on the large construction organizations which bid on this specification? One firm did this: It assumed that existence of a porous spot entailed the removal of a day's run and made its estimates in accordance with this assumption. More broadly, the effect is this: Contractors who have built up a great business by honest workmanship, and who are accustomed to have their honesty conceded by managers of large enterprises, resent such clauses as indicative of an assumed necessity to prevent cheating, and regard them as convenient weapons in the hands of engineers and inspectors for holding up the work and imposing needless penalties.

Lowest-Price Slavery

Another reason why the large contracting organization regards road work with indifference when other work is to be had is that price has too great weight with the public roads official. If any bidder's price is right and his bonds are unquestionable, he obtains the work, no matter how unfavorably he may compare with the large organization in reliability, equipment, resources and all else which ordinarily are held to be assurance of a successful business transaction. No doubt, the road official is largely the slave of the law in this matter, but this does not alter the facts nor their effect on the large contractor. He demands a fair profit for his work because he expects to put all his resources behind his promise that the purchaser shall get what he has asked for in quality and speed of construction. This guarantee he considers worth paying for, and he has small patience with the kind of client who shops about for the lowest bidder and trusts to the security of his legal hold on the bidder to obtain acceptable work.

It is, perhaps, not a generous thought, but the large contractor wonders if the road official is not just now inquiring whether, in some way, he cannot unload his own burden of rising prices on the contractor. A great many road projects for which the people have appropriated money were predicated on pre-war prices. Now the road officials find that they cannot deliver the mileages promised. Their attacks on the price levels of materials have failed to obtain reductions. Shopping about for low bids is a possible way out of the dilemma in which they have been involved. Contractors are free to impute to the road official this disposition to shift his burden, and the thought does not add inducement to road contracting as an opportunity for the large construction organization to extend its business.

Large construction firms, when they make bids, demand reasonable assurance that it has been definitely decided to award contracts and to award them promptly. An occurrance of recent date illustrates what happens too often. Bids were called for and received on a job amounting to about $150,000. A well known, large company was the low bidder and expected the award of the work. Later it was learned that the decision to proceed with the improvement had not been definite, and, when the prices were seen, the road officials concluded that they "would not go ahead at present." In other cases limiting prices are determined but are not published in advance. The reaction of large construction companies to experiences of this kind is fairly indicated by one which asserted that it was "becoming disgusted with the whole road game."

Most of the large construction companies which contemplate embarking on road construction expect to equip themselves on a large scale. A season's work will not pay them for the investment which they contemplate; they must see ahead a number of years of activity. To be specific, one large organization in estimating for a recent letting figured upon spreading its original plant outlay over five years. It could not otherwise have named a price which would have had a chance of being accepted. Contractors who plan in this far-sighted manner are the kind wanted in road contracting, but they frankly assert that they find little encouragement, in the attitude of road officials, for their broad planning. Road-construction plant is special plant. Few of its units are stock equipment of the general contractor who does railroad or heavy industrial work, and few of them can later be used in his general work. He must see the opportunity for continuous, profitable road contracting, or he cannot afford to invest in the special plant required.

Conclusion

Demonstration need not be carried further. If highway officials wish to enlist large general contractors in road construction, they can do so. Lacking normal outlets for action, these contractors are seeking opportunities in road construction. They will, for the moment, submit to the handicaps of road contracting. But if the road official wishes to retain these large organizations among the contractors at his command in prosecuting his large construction program, he must clear away the indictment which they have drawn against his methods. Let us be clear at this point. These large construction companies are not supplicating the road official to change his methods in their behalf. Indeed, they are, personally, very little concerned about his reform. Until he reforms, however, they shun extensive business transactions with him.

Suspected anxiety on the part of large contracting organizations to embark in road construction cannot be capitalized by road officials. There is no such anxiety. These organizations regard road construction merely as a possible but doubtful field. On the other hand, in the opinion of the contractors interviewed, the road official can proceed with success toward enlisting these organizations in road construction if he will: (1) Decide definitely before bids are asked that contracts are to be awarded, and then make awards promptly; (2) give weight to the contractor's resources and reputation for efficient work, instead of letting low price control; (3) adopt the practice of private industries in dealing with the contractor on a fair-price, good-construction basis, and (4) eradicate the practice of binding the contractor to honesty with meticulous, punitive restrictions, readily capable of being used unfairly against the contractor.

Designers of Louisville Lift-Bridge Machinery

Through oversight, the article in *Engineering News-Record*, May 22, 1919, p. 1007, describing the design of the new superstructure of the Louisville bridge, did not credit the firm of Waddell & Son, Inc., of Kansas City, Mo., and New York City, with the design of the towers and machinery of the 260-ft. lift span This firm acted as consulting engineers to the contractor.

Reline Mine Shaft on Steep Slope With Concrete

A Combination of Monolithic, Precast and Cement-Gun Methods Used in Old Shaft on Vermilion Iron Range

THE first steel-lined shaft sunk on the Vermilion iron range in Minnesota is being relined with monolithic concrete and precast-concrete lumber. This is the 1200-ft. Pioneer B shaft at Ely, Minn., which is on a slope of 70 degrees.

The sets forming the horizontal sections between which the vertical lath are placed were of 30-lb. steel rails, the lath being timber. Between some of the sets 1¼-in. wire cable was used, spaced on 6-in. centers, behind which timber was placed. On account of considerable wear and scaling of the rails, it was decided to secure a more rigid shaft by incasing the rails in concrete and putting in new steel dividers. The walls of the shaft are very irregular, so that the new concrete ranges in thickness from 4 to 24 inches.

For about 50 ft. from the top of the shaft, 3 x 10-in. concrete lath were placed between the sets, which are composed of 6-in. steel H-beams and are spaced 5 ft. on centers. Steel angles riveted on the inside of the sets hold the lath in position. Below this, to the 950-ft. level, the spacing of the sets is 4 ft., and the lining will be monolithic concrete. From the 1200-ft. level to the 950-ft. level, precast timbering was placed similar to that used for the first 50 ft. of the shaft.

Monolithic Concreting Continuous

Monolithic concreting was started from the 950-ft. level Oct. 1, 1917, and proceeded at the rate of about 50 ft. a week. Concrete is mixed in proportions of 1:5, the local, bank-run aggregate containing about 50% each of sand and stone. As much of the work was done in winter, a wooden shed was built, 28 x 112 ft. and 12 ft. high. The aggregate is brought in by teams, and men with wheelbarrows then carry the sand and stone up a runway to a ¾-yd. mixer.

In order to make the work in the shaft continuous, a 1-yd. auxiliary hopper for concrete has been constructed at one side of the head of the shaft. The wooden box on the mine skip is easily able to hold 1 cu.yd. When it comes to the surface for concrete, the shaft face of the auxiliary hopper is opened by a lever, and the concrete slides into a box. After it is lowered into the shaft, a slide valve covering a hole 8 in. square at the bottom of the box is opened, and the concrete slides into the forms through a flexible 8-in. pipe having sections 4 ft. long.

The upper or hanging side, and the ends or short sides of the shaft, are thoroughly clean, as water is pouring down practically all of the time. With a little cleaning on the bottom side, the walls are ready for concreting. About 75% of the time is required to clean the walls, to fix the forms, place the reinforcement and arrange the bolts needed in the shaft forms. The remaining 25% is used in concreting. After an 8-ft. section is prepared it can be poured in one day. Wire-mesh reinforcement is used on the ends and hanging sides, being cut into 4-ft. lengths and so bent as to come within an inch of the face of the concrete.

In concreting, 12 sets of steel forms are used on the bottom sides, but wood forms are used on the ends and hanging side. These wood forms are being left in place. The sections of steel forms, alternately 3 ft. and 1 ft. high, allow for putting in the dividers, which are built of 3-in. channels, 5-in. H-beams and I-beams being the ladderway and skipway, while a 3-in. channel and I-beam form the dividers between the skipways. These dividers are placed directly above or below the old 30-lb. rail dividers.

An ingenious method is used in moving forms. A tugger hoist is rigged up on a post across the shaft in the ladder and pipe compartment, from which a rope guided by a ring on a trolley runs to a block and then down into the shaft. By the attaching of the end of the rope to hooks in the forms, the latter are easily handled and shifted.

Speed of concreting is limited by the mixer, which handles 8 cu.yd. an hour to the 1000-ft. level. As this is done only part of the day, only one crew is used at the surface, one man dumping raw materials into the mixer, one man handling cement from the stockhouse, three men on wheelbarrows, one man controlling the machine and handling the water.

Three shifts a day of four men each are used in the shaft. All of the men were specially picked for this work, being of a higher grade of intelligence than the usual run of mine laborer.

Steam is obtained from the mine boiler house, and the temperature in the shed is kept during cold weather at about 60°. A bare steam pipe along the wall helped to warm the stone and sand.

The cement-gun system is proposed for places where the hanging or upper side is only a few inches deep, as there is some question whether monolithic concrete of that thickness will adhere to the upper side of the shaft. Up to Jan. 1 the cement-gun had not been used, and for 100 ft. around the 700-ft. level the whole shaft was monolithic. On the bottom side the concrete extends an inch beyond the old steel rails, while on the hanging side and ends it extends ½ in. beyond the steel, giving a solid concrete face on all four sides. Plans for all this work were made in the Duluth office of the Oliver Iron Mining Company.

Comparison of Blows of Dull and Sharp Drill Points

ROCK drill points are the least effective and have the least penetrative results, blow for blow, when they strike the rock with most force and the shock is felt the most. This statement is made by Frank Richards in an article in *Engineering and Mining Journal* of Apr. 26, 1919, p. 735, where the apparent paradox is explained by the fact that with equal imparted energy the dull drill-bit is stopped more quickly than the sharp one. This the writer believes to be the cause of the breaking of many bits. A short abstract of the paper follows:

When impact is figured, the force of the blow struck is proportional to the suddenness with which the propelled mass is arrested. This may be clearly illustrated by the case of a reciprocating piston drill. Assume a drill with a piston 3 in. in diameter and a stroke of 6 in., and that in the working stroke of the piston it is driven the entire distance by an effective air pressure of 50 lb. per square inch. The area of the piston is almost 7 sq.in. As the assumed stroke of the piston is ½ ft., the resulting energy is $7 \times 50 \times \frac{1}{2} = 175$ ft.-lb.

The resistance will, of course, be greater in proportion as the distance in which the force is dissipated is shorter. Thus the resistance required to overcome 175 ft.-lb. of imparted energy would be 6 $\times$ 175, or 1050 lb., say 1000 lb., if the stoppage occurred within a distance of 1 in. Then, 4000 lb. of resistance would be required to stop the movement within $\frac{1}{4}$ in. and 16,000 lb. or eight tons, if within $\frac{1}{16}$ inch.

A penetration of $\frac{1}{16}$ in. approximates rock dri.. cutting conditions. Thus, at the rate of several hundred times a minute eight tons are applied and alternately stopped entirely. The rock strikes the bit with the same force as that with which the bit strikes the rock—the force must be precisely equal in each direction from the point of contact—and the greater the force at any instant with which the bit strikes the rock, the greater also must be the reacting force taken up in internal resistance in the body of the bit. The higher this reacting force the more likely it is that the bit will break.

Limit of Wear Should Be Fixed

Drills must wear, but the limit of permitted wear should be sharply defined, and systematic maintenance of bits in sharp condition should be recognized as the most profitable investment possible in connection with rock-cutting operations. In this connection power-drill sharpeners are to be commended as giving incomparably greater efficiency, as compared with hand sharpening.

The above theory was strikingly illustrated in a recent test, when it was found that the breakage in bits was very high, 10 bits being broken in a day's run. In every case it was found that the broken bits had become so dull as to lose their cutting power. In the next day's run care was taken to change the bit as soon as cuttings ceased to drop regularly from the hole. With this system it was found that no drill bit was broke in the day's run, with the exception of one dull bit which was used as a test and which broke within two minutes.

Highway Transport Engineering—a New Technical Field

Breadth of Training Necessary for the Transport Engineer—Many Problems to Be Solved—Suggested Course of Study

A BREADTH of training far more comprehensive than has been considered essential for many technical branches will be required for the proper equipment of the highway transport engineer, according to Prof. Arthur H. Blanchard, of Columbia University. In dealing with this topic before the annual meeting of the National Highway Traffic Association in New York, he outlined courses of study to be followed in preparing for this profession, linking them up with the problems which must be solved. Having sketched briefly the phenomenal expansion of highway improvement in highway transportation in the United States, and having contrasted the problems met with here with the experience in England, where highway-transport regulation came to a head some years ago, Professor Blanchard continued:

The development of highway transportation creates a demand for men having knowledge of and trained in a new technical field. Fundamentally, highway-transport engineering deals with the science, art, economics and business of the highway transportation of passengers and commodities. Breadth of knowledge is essential, as the highway-transport engineer must, in many fields, deal with social and economic conditions, and must always have before him the fundamentals of sound business methods.

In the opinion of some, highway transport may not be considered as belonging to the field of technical training and education. On sober thought, however, it will be seen that this branch of knowledge comes well within the classic definition of engineering embodied in the royal charter of the Institution of Civil Engineers of Great Britain, which, in part, is as follows: "The art of directing the great sources of power in nature for the use and convenience of man as the means of production and of traffic in states both for external and internal trade."

Comprehensive courses in highway-transport engineering to be offered by educational institutions should include the following basic subjects: Economics, political economy, social science, business and contract law, scientific management, business organization, cost accounting, interstate commerce and marketing and distributing systems.

What Highway-Transport Engineer or Manager Should Know

The highway-transport engineer or manager should have a knowledge of all of the following special subjects:

History of American transportation and rural development; English highway transport methods and legislation; interrelationship of highway, railway and waterway transportation, including influencing factors of distances, rates, kinds of freight and equipment; port, terminal and warehouse facilities; interrelationship of highway transport, good roads and rural development; the "back-to-the-farm" movement, which is a function of three fundamentals—namely, building of systems of good roads, utilization of highway transport, and establishment of economic distribution from producer to consumer.

He should also have a knowledge of the subjects under the following heads:

American Highway Traffic Legislation—National, state, county, township and municipal laws, licenses, taxes and traffic regulations, especially those covering speeds, weights and dimensions of motor trucks, trailers and motor buses.

Fundamentals of Highway Engineering Affecting Economic Highway Transport—Administration of highway departments; highway systems; location, drainage, foundations, grades, curves, widths and shoulders of highways; characteristics of different kinds of roadway, with particular reference to traction; snow removal; guard rails, culverts and bridges; highway signs.

American Highway Transport Methods—Comparison of horse and motor transport, municipal haulage, muncipal delivery systems, store-door delivery, intercity haulage, long and short haulage outside of cities, rural motor express, return-loads bureaus, motor-truck parcel post, plant and factory haulage, Army transport methods, horse transportation methods; efficient methods of packing, handling, loading and unloading raw and manufactured materials; highway transport management; fundamentals of cost of highway transport, cost and record systems; organization of motor-haulage companies; labor for highway transport.

Motor-truck, Motor-bus, Tractor and Trailer Mechanism, Operation, Inspection, Maintenance, Repairs and Cost Data—Adaptability of different types of trucks and bodies; disadvantages of overloading and overspeeding; economic utilization of tractors and trailers; garages; accessories, such as tires, fuels, lubricants and mechanical devices.

Transportation Surveys—Investigations of highway routes, highway-transport legislation, traffic regulations, rural and urban transportation opportunities, competing carriers, including railway, waterway and other highway-transport facilities, and all other factors which may affect the transportation business which it is intended to establish.

Engineering Standards Committee to Reorganize

Proposes to Become an "Association" to Include a Wider Field of Work — Membership Open to All Interested Bodies

A REVISED constitution was adopted by the American Engineering Standards Committee at a meeting held May 17. This new constitution has been submitted for ratification to the councils of the five societies which formed the committee, the American Society of Civil Engineers, the American Institute of Electrical Engineers, the American Society of Mechanical Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society for Testing Materials. The proposed reorganization developed from a meeting of organizations interested in formulating safety codes, held at Washington on Jan. 15, at which the American Engineering Standards Committee was described by its chairman, Prof. C. A. Adams, and a proposal was made to have the safety-code work carried on under the rules of the committee. It was objected, however, that the safety-code conference could hardly be expected to submit its work for approval to a committee on which its own members had no representation. In order, therefore, to bring about a form of organization with broader character of representation, the revision of the constitution was formulated.

Details of the contents of the new constitution are withheld by the committee. Essentially, the reorganization, which changes the name "committee" to "association," provides for increasing the body by taking in representatives from other organizations than the five founder societies and the three Government departments originally named, and fixes the dues of the societies represented. The new constitution also makes it optional with member societies to submit to the association for approval any or none of the standards which they may formulate. Commercial and scientific or noncommercial standards are governed by somewhat different rules concerning the constitution of committees.

Explanatory Statement by Committee

In announcing its action, the Engineering Standards Committee states:

It is anticipated that in nearly all cases the approval of standards and committees by the association will be requested. In case it is considered advisable, the association is authorized to call a meeting of those who would be interested in the formulation of a new standard or the revision of an old one, to select one or more sponsor societies. The sponsor society or societies will appoint a sectional committee to formulate or revise the standard. This sectional committee will report to the sponsor when its work is completed. The sponsor may then request the association to approve. The association deals only with the sponsor and acts only at its request.

In further explanation of the manner of action of the proposed association, it is stated:

The association thus acts only to bring together those interested in a common object, and, when they have completed their work will at their request certify that it has been done in such a manner as to justify its adoption. Nothing revolutionary is proposed; it is merely an extension of present practice. The executive committee of the American Society for Testing Materials now passes on the composition of committees, ascertains that their conclusions are substantially unanimous, and, if so, reports them to the society for acceptance or rejection. The association does the same for groups of organizations. Its board of directors performs the same functions as the executive committee of the American Society for Testing Materials, and the association as a whole accepts or rejects. It neither selects sponsors nor sectional committees; it does not consider the subject matter of a standard, nor the procedure under which it is arrived at, except that it requires sufficient information from the sponsor to show that the conclusions are substantially unanimous and that the sectional committee is balanced and representative.

It may be asked whether there is sufficient reason for the existence of the association. This, naturally, has been carefully considered, and it is the unanimous conclusion of the committee and of all those who have been consulted who have been active in standardization work that such an organization is urgently needed. In the past there have been many occasions when two or more organizations have formulated standards for substantially the same thing. Often these differences have been very slight, but neither has been quite acceptable to the other party. In the majority of such cases, if these organizations had been brought together at the start they could have agreed on a standard that would have been satisfactory to both. The American Engineering Standards Association will furnish a means by which any organization intending to define a standard can readily ascertain what others are interested, and should be consulted in regard to it. At present there is no such means.

Expect Present Organizations To Ask Assistance

There is nowhere anything approaching a complete list of the organizations doing standardization work, much less any list of the standards proposed or in preparation. The enormous advantage of having any standard generally accepted, and the much greater probability of accomplishing this if it is prepared under definite conditions that have proved effective in the past, will, it is believed, cause most of the organizations engaged in such work to ask and receive the assistance of the American Engineering Standards Association. It provides definite machinery for securing coöperation and preventing duplication of work. It establishes definite rules securing the absolute autonomy of any group engaged in the development of standards, and insures that this group shall receive full credit for its work. With the assurances of coöperation that the American Engineering Standards Association has already received, we believe that there is no question of the advisability of forming the more broadly representative association. Several organizations have already presented requests for the approval of existing standards, and we are informed that many others only await the notification of the committee that it is fully organized

It has been impossible to make any public statement of the committee's plans until they had been definitely formulated. This, we feel, has now been accomplished, and we can therefore state what it is hoped to accomplish and the methods proposed for the purpose.

G. C. Stone, vice-chairman of the committee, is directing its work for the time being. C. B. Le Page, 29 W. 39th St., New York City, is acting secretary.

Class in Art for Engineers

According to the *Bulletin* of the Art Institute of Chicago, a member, who is an engineer by profession and the head of a large engineering company in Chicago, came to the institute over a year ago with the desire that a class be formed for the men in his office, that they might become familiar with the collections in the Art Museum and develop a love of and desire for beauty. This course held an interested group and has just been organized for another year, meeting weekly, with attendance voluntary, the extra time being made up at the end of the day.

Mechanical Handling the Feature of Concrete Pile Yard

At Norfolk Army Base Both Bearing and Sheet Piles Were Rapidly Turned Out in Plant at Which Manual Labor Was Reduced to a Minimum—Concrete Mixed Alongside Each Pile

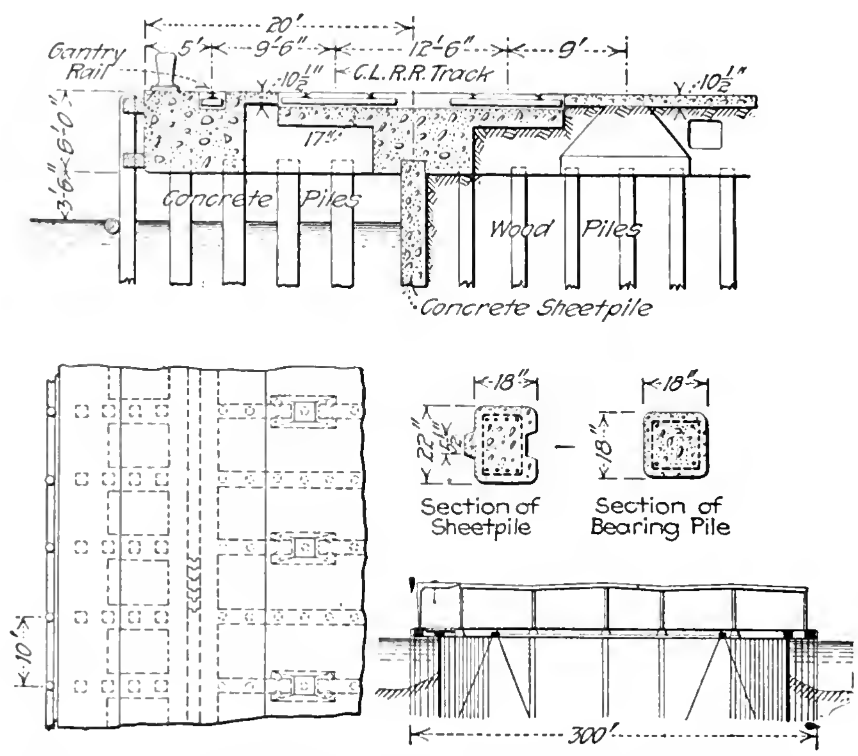
OVER 7000 reinforced-concrete bearing and sheet piles had to be cast in the summer of 1918 for the Norfolk Army supply base. In order to insure the completion of the contract in the short time allotted, there was built at the site a special pile-casting yard of extraordinary elaboration and size, and the casting was completed there in the required time. In all, there were cast 7442 piles, using 35,200 cu.yd. of concrete and 6400 tons of reinforcing steel, in the four months during which the plant was in operation. The highest number of piles cast in a 10-hour shift was 141, representing 620 cu.yd. of concrete. Every advantage was taken to substitute mechanical handling for manual labor.

The Norfolk Army supply base has as an integral part two piers, each 300 ft. wide and 1328 ft. long. On account of the nature of the ground and as a protection against the teredo which infests those waters, the type of section shown in the accompanying drawing was adopted. This, it will be seen, comprises a fill over the middle 260 ft. of the pier, retained by reinforced-concrete sheet piles, with wooden piles in the fill portion and an extension platform, carrying a gantry crane, with reinforced-concrete bearing piles. There were, therefore, two types of concrete piles to be cast, a rectangular tongue-and-groove sheet pile 18 x 22 in. in section, and a bearing pile 18 in. square.

The sheet piles varied by 5-ft. increments in length from 35 to 65 ft., while the bearing piles varied from 50 to 65 ft. Special sheet piles were also cast, consisting of corner piles, double-tongue and double-groove piles, closure piles 15 in. wide, and wedge piles narrowing from 18 in. at the top to 9 in. at the bottom. The bottom of the sheet piles was beveled 6 in. in 2 ft. on the groove side to facilitate crowding the piles together, and the bottom of the bearing piles tapered in 8 ft. from their full section to 10 in. square. The reinforcement consisted of a 1¼-in. deformed bar in each corner with ¼-in. hoops, spaced as required in the design. Additional reinforcing bars were used to take care of stresses set up by the methods that were required in handling the piles, the length and size of the bars depending upon the length and weight of the piles.

Two Yards Had to Be Built

A number of views of the yard in which the piles were cast are shown, as well as a drawing of the layout. As shown on the sketch, there were two yards, an east yard and a west yard, on either side of a central main-line track from which the aggregate was delivered. The details of the two yards were somewhat different, but in both every effort was made to magnify the use of machinery on account of the labor shortage at the time when the work was carried out. Both yards are laid out in a straight line controlled by straight tracks running parallel to the main delivery track. In the east yard the steel-fabricating shed was at one side of the yard, delivering reinforcement to the forms on the concreting platform. In the west yard the steel-fabricating shed was at the extreme end of the yard. In the east yard the steel and the finished piles were handled from a steel gantry crane spanning the casting platform. In the west yard this work was done by a locomotive crane. Both yards used a traveling concreting bridge, but the east yard had its aggregate fed from an aggregate car traveling on a track from the storage bins, whereas in the west yard there was a plank runway on which man-handled wheelbarrows transported the aggregate. The entire casting yard is about a mile from the water front on a comparatively level area. The foundation

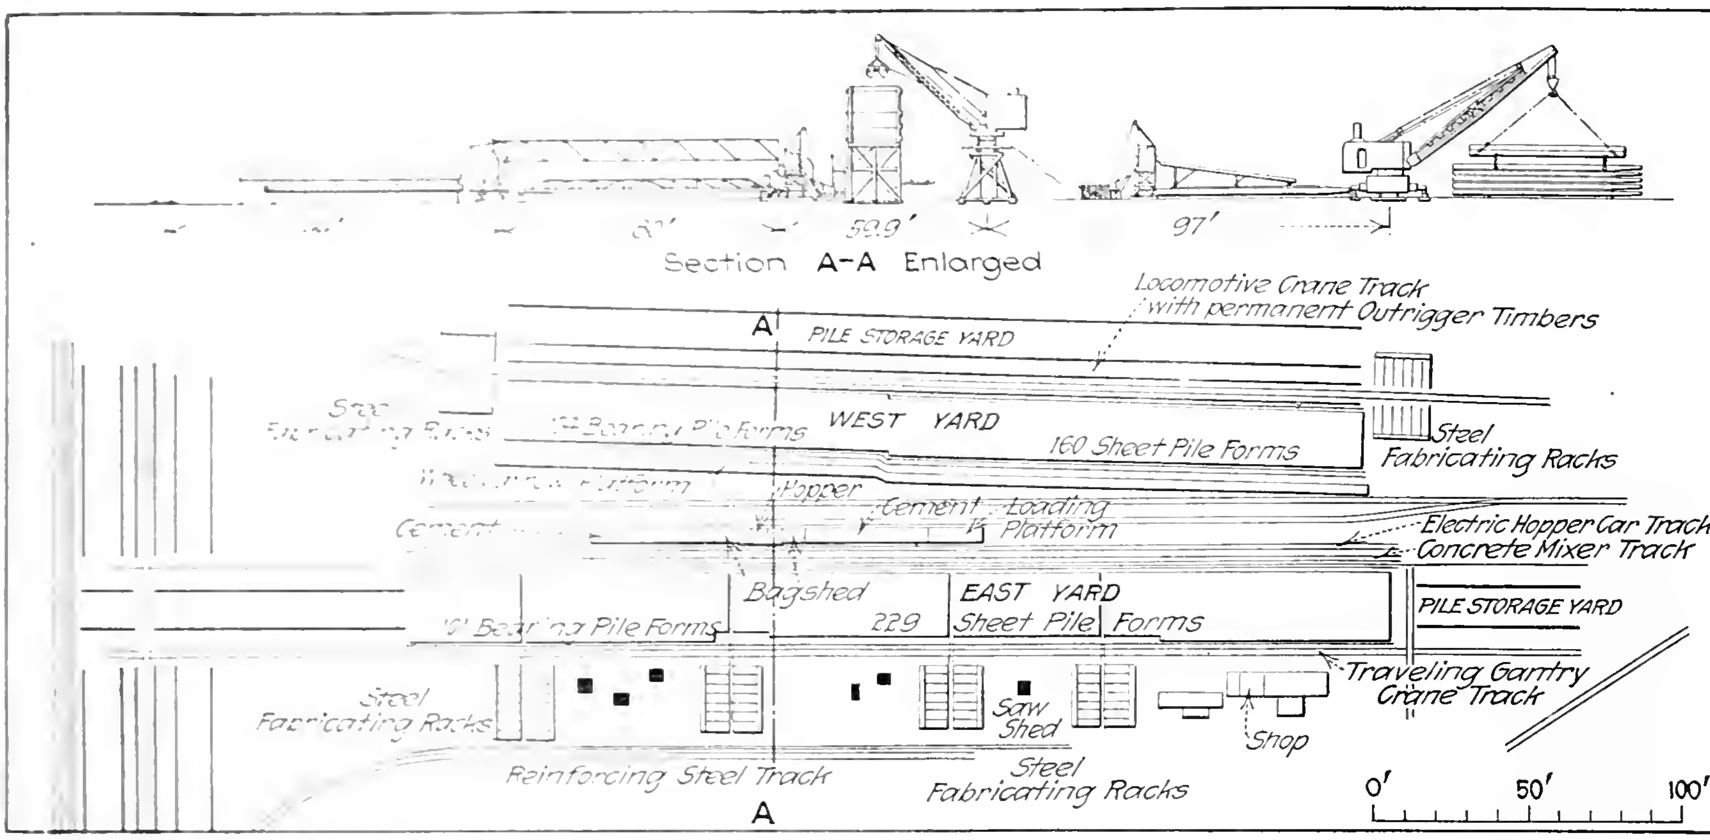


DETAILS OF CONCRETE PILES USED ON THE PIERS OF THE NORFOLK ARMY SUPPLY BASE

upon which the forms were built was substantial and unyielding, which permitted the casting of the piles very straight and true.

The reinforcement was fabricated on special racks in the sheds alongside the pile yards. These racks, as shown in one of the views, were placed about 4 ft. above the ground and were supported on 2 x 4-in. stakes and stringers. Strap iron was laid on top of the stringers to facilitate the movement of the steel without unduly wearing the supports. Fabrication was carried on under the shed on cantilevered brackets raised to such a height as to carry the two upper rods the proper distance above the runway stringers. When necessary, these longitudinal rods were spliced together and thoroughly wired after splicing. The ¼-in. hoops were then swung into place and fastened to the longitudinal rods, using No. 12-gage annealed iron wire or a special connection. When the reinforcement was finally fabricated it was pushed off the brackets onto the stringer and slid along until it reached the ends of the racks.

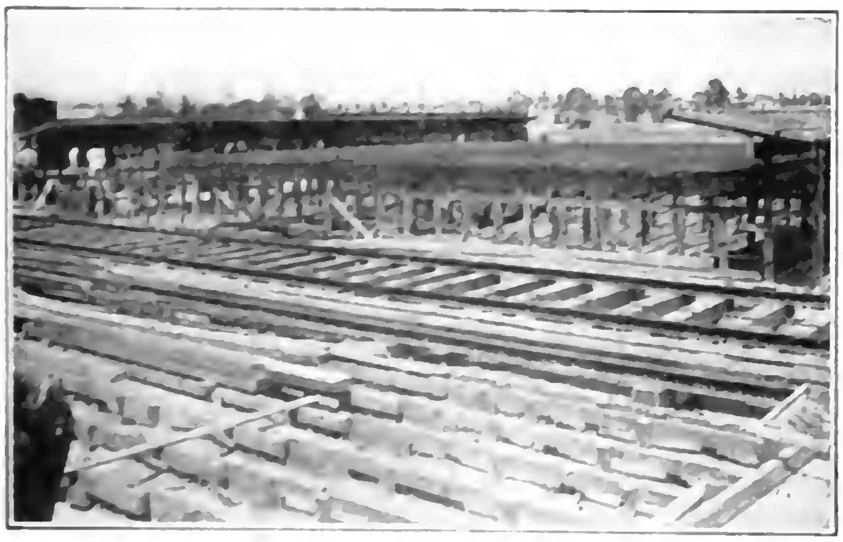
In the east yard fabricating shed the assembled reinforcement was dropped onto a long flat truck running on a narrow-gage track parallel to the direction in which the steel was fabricated and pushed out onto the casting platform, to be set in place by the gantry crane. In the west yard shed, as shown in the general view of the yard, a standard-gage track ran between the two halves of the casting shed, and the steel could be transported where required by the locomotive crane traveling on the track. A rigid beam with multiple supports was used in lifting the steel.



GENERAL LAYOUT OF CONCRETE PILE-CASTING YARD AT NORFOLK ARMY SUPPLY BASE

The forms in both yards were of cut lumber resting on continuous fills. The bottom forms were stationary, and the side forms were set and wedged at the bottom as required, the tops being set to line with templets, and 1 x 2-in. nailing strips were nailed on top of the forms to keep them from moving. In the east yard the casting platform on which these forms were placed had on either side a single rail and a track which carried, respectively, a pile-handling gantry of steel framing and a wooden concreting bridge.

The operation of concreting in this yard was carried on about as follows: The material was brought in on the main track, and the sand and gravel unloaded from an elevated trestle by gravity. A locomotive crane operating on this trestle lifted the sand and gravel from the ground where it had been dumped to the bins alongside of the east yard. From these bins the material was deposited by gravity to a measuring hopper, where the proper proportions of sand and coarse aggregate were measured and mixed, and from these measuring bins the coarse aggregate ran by gravity into a special aggregate car which traveled on a track running alongside of the aggregate storage bin. This car was run by electricity to the mixer, which was also moved on a parallel track and which was at the time of concreting placed immediately opposite the pile to be poured. Over this pile was the concreting bridge. The batch in the aggregate car was run by gravity into the skip of the mixer and there mixed. After being mixed the concrete ran by gravity into the car supported on the concreting bridge which ran immediately over the pile. This car had a bottom-drop door through which the concrete was deposited at any point in the length of the pile.



REINFORCEMENT FOR PILES WAS FABRICATED UNDER SHED AND MOVED TO CENTRAL TRACK

This method of handling the material permitted the concrete to be mixed immediately over one end of the pile, and there was no danger of the aggregate becoming separated by reason of transporting the concrete a long distance. As the yard was over 1800 ft. long this difficulty in so hot a climate in the summer would have been very hard to overcome. By the method employed the concrete could be deposited in a very few seconds after it was out of the mixer.

The electric-driven hopper car, which delivered the dry batch from the central hopper to the mixer, consisted of a hopper which discharged directly into the loading skip of the mixer. It was mounted on trucks, and the motive power was furnished by a 15-hp. motor geared to one axle, and with a street-car motor control. The mixer was mounted on a car which was moved along by a rope from a hoisting engine or by use of a pinch-bar. The two wooden concreting bridges, with a span sufficient to cover the longest pile, were designed and made on the work to carry the concrete car the full length of the pile. The trusses were built of timber and rods.

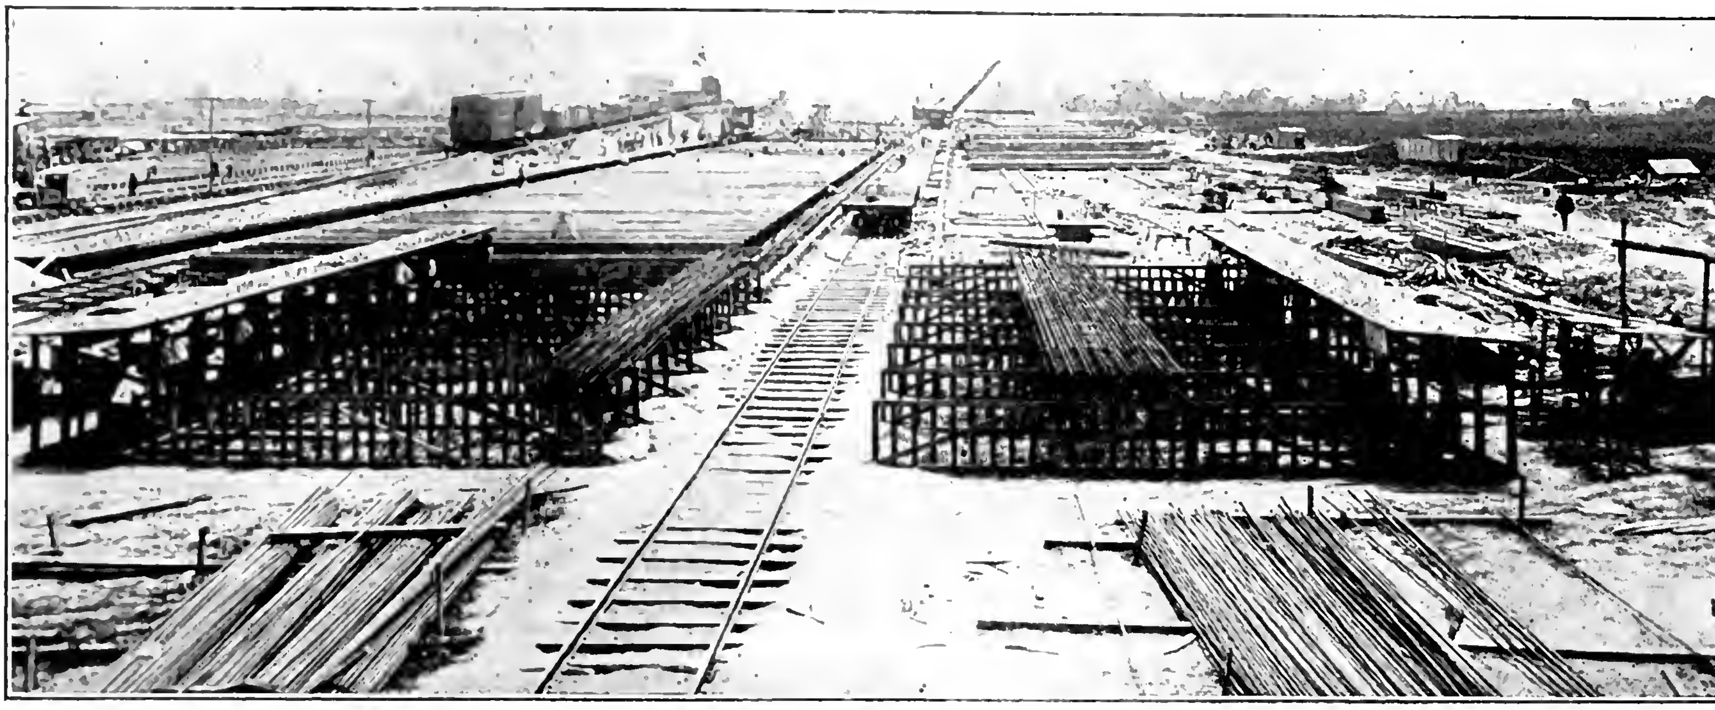
After the piles were cast they were handled by one of the two steel gantry cranes, which were propelled by a three-drum hoisting engine mounted on a car at one end of the pile. Two drums were used to pull the car and the gantry back and forth. The third drum was used to raise and lower the pile, the rope being reeved through a series of tackles which lifted the beam at four points. Adjustments were made at each of the four points by means of turnbuckles. The beam was made up of two 18-in. I-beams with their flanges riveted together.

Cement was handled in different manners. Wherever possible it was used directly from the cars to the dry-batch car, in order to avoid rehandling, but a cement house was provided holding a number of cars of cement as an emergency to take care of any situation.

In the west yard, which was built after the east in order to increase the output on account of the developing program of construction, additional gantry cranes were not available, so the work of handling the reinforcement and the finished piles was taken care of by a 150-ton locomotive crane mounted on a standard-gage railroad track. In this yard no piles longer than 55 ft. were cast. The mixing plant consisted of two ¾-yd. mixers, one driven by steam and one by electricity, mounted on elevated trucks traveling on a standard-gage track.

The steam mixer discharged into an inclined chute with removable bottom section, the chute being mounted on 4-in. cast-iron casters traveling on a movable plank track. The electric mixer had a concrete bridge and bottom-dump bucket, similar to those used in the eastern yard, except that, being shorter, this one was built as a unit with the mixer truck and traveled with it.

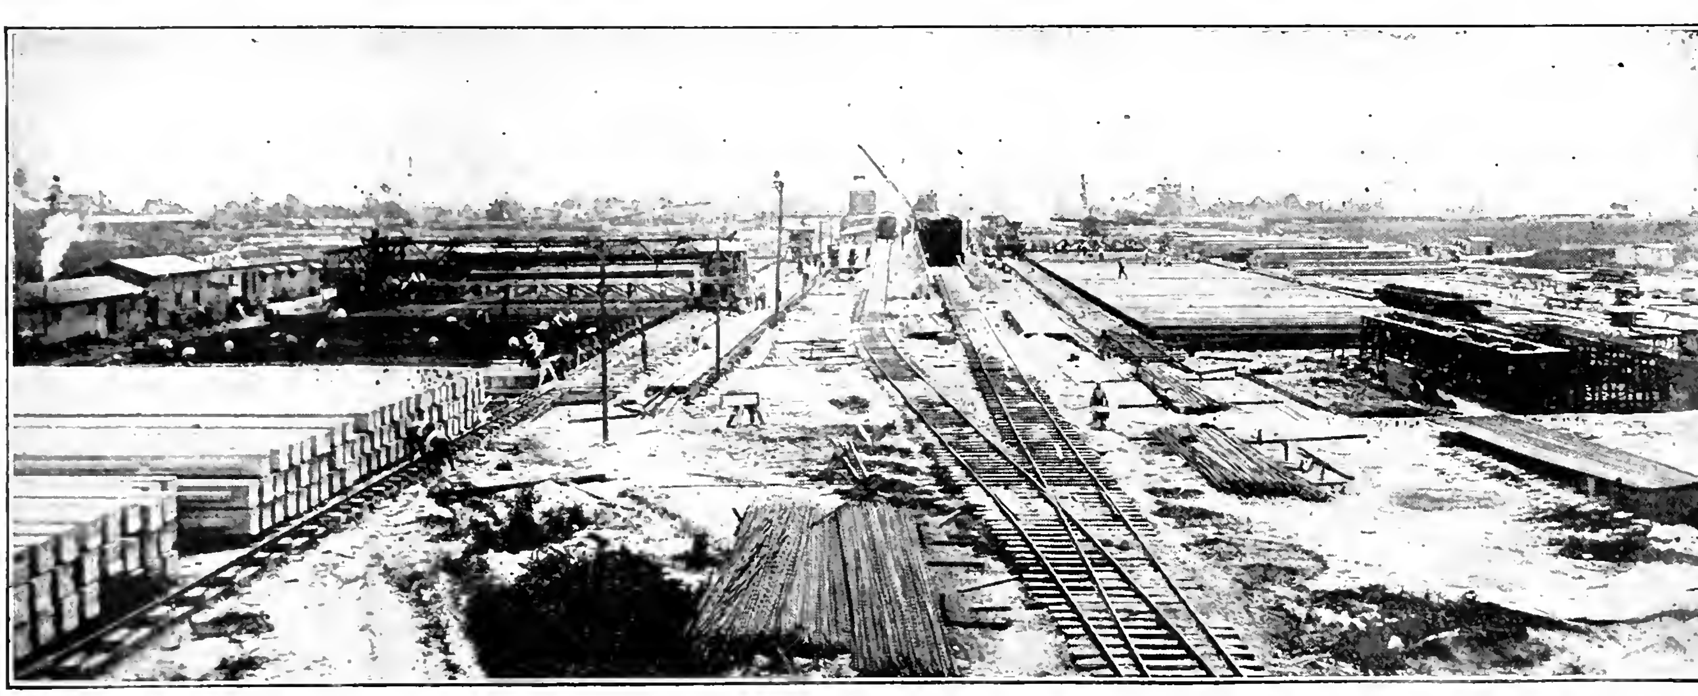
Both mixers were served with concrete material by wheelbarrows operated on a track runway about 5 ft. high along the edge of the storage pile. Cement was used directly from cars when possible, or was delivered by wheelbarrows from the east yard cement shed through two alleys left for that purpose in the storage pile. In the west yard the locomotive crane handled the finished piles to the pile storage on the other side of the track.



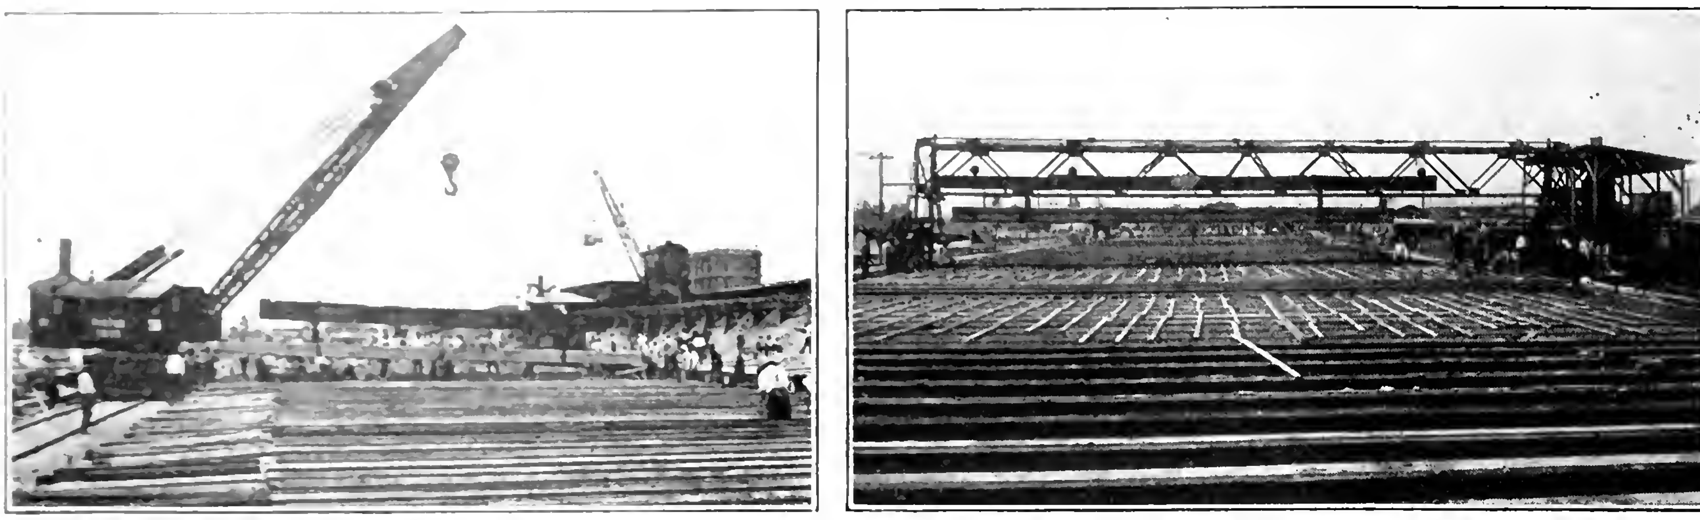
LOOKING DOWN LOCOMOTIVE-CRANE TRACK IN WEST YARD; FABRICATING RACKS IN THE FOREGROUND. AGGREGATE TRESTLE IS AT THE LEFT

The storage yard for the curing of piles was carefully prepared, in order to prevent damage to the piles due to uneven settlement. Two rows of standard railroad ties were set 2½ ft. c. to c. on a graded bed. On these ties continuous 6 x 12-in. timbers laid on the flat were placed about 36 ft. c. to c., or about under the pile-lifting point. Piles were usually stacked on these timbers four high with the gantry cranes and five high with the locomotive cranes. There was about 4-in. clearance between the stacks of piles, and successive layers of piles were separated by 3-in. timbers laid on the flat.

During exceedingly hot weather the piles were sprinkled while in the storage yard, to aid in curing. The storage period was about three weeks, although



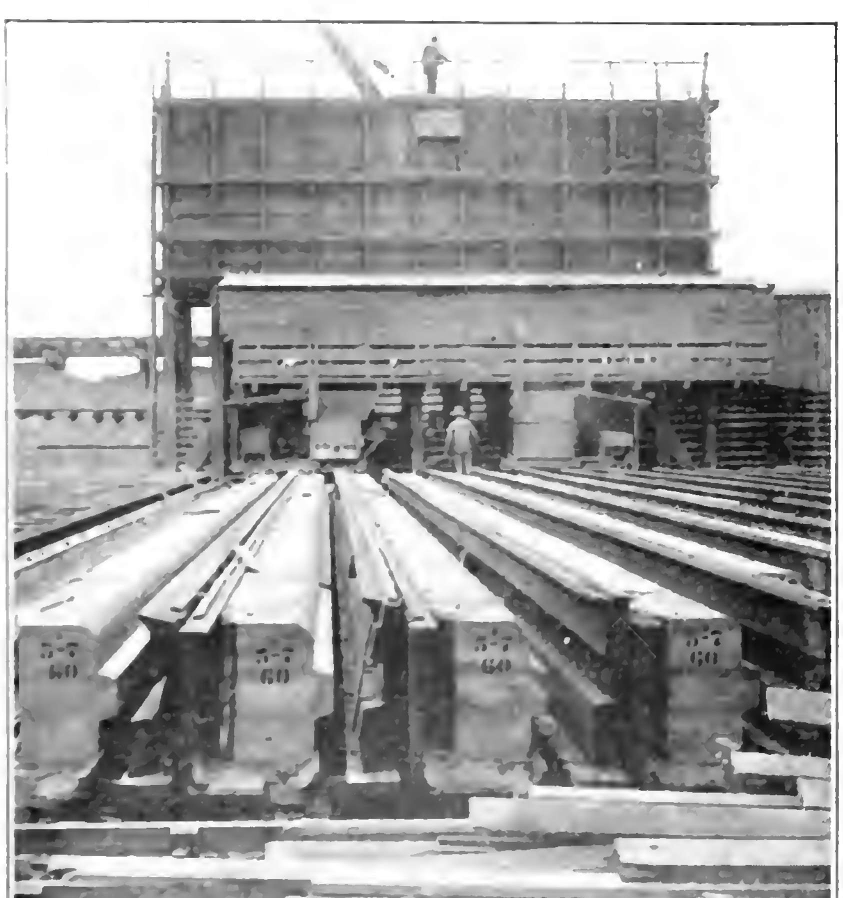
LOOKING DOWN CENTER OF PILE-CASTING YARD; EAST YARD AT RIGHT, WEST YARD AT LEFT. AGGREGATE TRACKS IN CENTER



HANDLING PILE WITH LOCOMOTIVE CRANE IN WEST YARD; WITH STEEL GANTRY IN EAST YARD

many piles were driven successfully in 14 days, and in the case of wedge piles they were driven in seven days without any damage whatever. In transporting the piles to the work they were loaded on heavy, steel-body flat-cars of 80-ton capacity, five or six to the car. The usual trainload consisted of three loaded and four idler cars. Some of the piles weigh as much as 13 tons.

Owing to the great demand by Government improvements in the neighborhood for coarse aggregate, it was necessary to use different kinds of material, crushed granite, limestone, and washed bank gravel being used at various times, but all in the proportion of 1:1½:3. On account of the small space between the reinforcement and the forms, it was necessary to use a stone of small size, the best result being obtained by a maximum diameter of 1 in. The bulk of the fine aggregate was coarse, washed bank sand. The workmanship in connection with the placing of the concrete was very thorough. Spading was continually carried on, and no expense was spared to be sure of good quality of concrete. Running it too wet was not permitted, because the concrete was deposited from the car immediately above the place where it was required.



HEAVY CONCRETE SHEETPILE ON CASTING PLATFORM

Electric-driven aggregate cars in background in front of material storage bins

The work was done by the Raymond Concrete Pile Co., of New York, for the United States Government, with Porter Bros., of Wilkes-Barre, Penn., as general contractors. Col. M. A. Butler was constructing quartermaster in charge of the work and A. O. Leach and G. F. Bowlus were supervising engineer and division engineer, respectively, for the Government. A. F. Barnes was general superintendent for the Raymond Concrete Pile Company.

Aerial Wire-Rope Conveyors to Feed Railways and Ships

IN SPEAKING on the value of "Aërial Wire Rope Conveyors as Feeders for Railway and Ship Lines," before the engineering section of the Pan-American Commercial Conference, Walter C. Kretz dwelt on their ability in developing regions at present inaccessible, on the west coast of South America. In his opinion they will solve many difficult and, in fact, otherwise unsolvable problems of transportation in that region.

After giving a description of the various types of aërial cableway, together with the limitations of each, he cited examples of their successful use under South American conditions.

One advantage of cableways over other means of transportation is that they can operate over very steep grades. An installation in Africa was mentioned which is operating over an 86% grade. Principal among the examples described is one in the Argentine Republic. It extends from the end of the railway line at Chilicito to Upulungos, a mining town 34.67 km. (21.5 miles) away, and 3510 m. (11,513 ft.) higher in elevation. On the down trip it carries chiefly ore, at the rate of 40 tons per hour. Passengers, miscellaneous supplies, machinery, etc., are also transported in both directions.

According to Mr. Kertz, this installation is at present the longest aërial cableway in operation in the world. It has nine separate sections, with intermediate terminals where transfer from one section to the other is made automatically.

Ship loading and unloading in open roadsteads, by means of building an island pier well out and transferring the passengers and freight by means of cableways, were also touched upon.

The speaker said that it must not be thought, because the installation is cableway, that it can be built for the mere cost of the cable and engines. It is doubtful if any such installation can be made for less than \$10 per meter (3.28 feet).

Labor Turnover High on Two War-Time Contract Jobs

Short Average Stay of Both Skilled and Unskilled Laborers Decreased Efficiency and Increased Cost of Work

By Sidney G. Koon
Walter B. Snow and Staff, Boston, Mass.

FLOATING labor undoubtedly contributed much to the difficulties of war-time construction noted by H. C. Turner in his article in *Engineering News-Record*, of Apr. 24, 1919, p. 815, if the experiences of most contractors was the same as that of the Aberthaw Construction Co., of Boston, on two large Government contracts, as well as their experience through 1917, on work of which none was done for the Government. All of these jobs, Government and otherwise, were done on the cost-plus basis.

An analysis of the labor situation on 15 jobs (in three states), which were started and completed in 1917, shows a total of 7179 men hired; while the sum of the 15 separate peaks, showing the maximum number of men on a job, was only 2812. The ratio between the number of men hired and the sum of the 15 peaks is 2.54 to 1—or, in other words, five men were hired for every two men at time of greatest employment. More than two-thirds of all the men who left of their own accord simply quit without giving any reason.

Taking the whole experiences of the year in connection with the length of time during which individual men worked on a job, it is found that 18.9% of the men worked three days or less; 32.4% (practically one-third) worked not more than one week. More than two-thirds of the total, 68.3%, were on the job less than one month. Of the total number employed, the "exits" were distributed as follows:

Transferred to other jobs		1882
Quit, no reason given	2174	
Left for another job	321	
Left because of sickness	139	
Left for family reasons	91	
Dissatisfied with job	78	
Leaving town	120	
Gave notice	51	
Dissatisfied with pay	38	
Enlisted or drafted	103	
All other reasons	91	
Total resigned		3206
Dismissed as incompetent	415	
Refused to obey	95	
Trouble-makers	23	
Drunk	14	
Not adapted to work	17	
Refused to work	73	
Struck for higher wages	12	
All other reasons	148	
Total dismissed		797
Laid off on reducing force	290	
Laid off, no stock	10	
Laid off, job finished	994	
Total laid off		1294
		7179

Divided according to length of service on the job, the men were grouped as follows:

3 days or under	1351
4 to 6 days	980
7 days to 2 weeks	1359
2 to 4 weeks	1219
4 to 6 weeks	750
6 to 8 weeks	458
More than 2 months	1062
Total	7179

A more detailed analysis has been made of the work at the two jobs listed below, both of which were for the Government and both carried on under high pressure.

At the Squantum works of the Bethlehem Shipbuilding Corporation, Ltd., where the Aberthaw Construction Co. erected in record time the largest destroyer-building plant in the world, the job was started in the second week of October, 1917, and was practically finished in June, 1918. About $13,000,000 was spent in providing a complete plant with 10 building ways. There was no war construction work going on in Boston, and the district had an excellent labor supply. For the first 10 weeks the men had to walk from 15 to 25 minutes from the nearest railroad or trolley line to get to the job. This was during the early part of an exceptionally severe winter, the daily mean temperature during January never going above the freezing point. A total of 10,300 men was hired on this job. The employment peak, Jan. 12, was 4200 men, showing a relation of the total number to the peak of 2.48 to 1. It will be noted that this is almost identical with the experience of the company on the 15 non-war contracts of 1917.

Of the total number of men employed, 3050 (29.6%) quit in one week or less; 2078 (20.2%) quit in seven days to one month; 1600 (15.5%) quit during the second month of employment; 1209 (11.7%) during the third month, and smaller numbers during succeeding months. These figures show that 77% of all the men hired for the job were gone in three months.

Of the total number of men hired 6219 were laborers; 31% of these, or 1936 men, worked one week or less, and nearly 55% (3344) worked not to exceed one month. The record of the laborers is thus seen to be somewhat worse than that of the men as a whole. In fact, if we deduct the number of laborers from the total number of men, we find that 1114 of the 4081 other men quit during the first week, this being 27.4% as compared with 31% for the laborers. Similarly, 43.6% of the higher-grade men had left the job inside of the first month of employment, as compared with 54.8% of the laborers.

Maryland Shipyard Had Worst Labor Turnover

The $3,000,000 job at Sparrows Point, also built by Aberthaw, 14 miles out of Baltimore, showed a radical difference in turnover of labor. The total number of men hired was 5245, of whom 3562, or 67.9%, had quit at the end of the first week of employment. Additional men to the number of 1070 left before the first month elapsed. This total is no less than 88.3%, by far the worst labor mortality in the history of the Aberthaw company. The number of men on the day of the peak was 836. The ratio of the total number hired to the peak number was 6.27 to 1, practically double the highest of any figure reached among the 1917 contracts.

The Sparrows Point job was started in June, 1918, and ended in February, 1919. It was in a district in which war contracts totaling many millions were under way, and was at the extreme end of the railroad line running out from Baltimore, which passed seven other large contract jobs. Camp Holabird was the nearest to Baltimore; in succession a munitions plant, a large sewer, water and gas contract, two Government housing projects and two Government shipyards were passed before the Sparrows Point job was reached. On the last-named four contracts, free transportation to and from Baltimore was furnished; but this was not the case on the Aberthaw job. Consequently a barracks was built and a restaurant established on the job to take care of the men who were not residents of Baltimore.

The Baltimore district reported a constant shortage of labor because of the large number of projects under way in the vicinity, and the United States Employment Service, from which the laborers for the Aberthaw job were obtained, had to serve the insistent demands of all. By the time laborers reached Sparrows Point they had made the rounds of every construction job in the district.

From the above cases it will be noted that the work at Squantum, with bad transportation and exceptionally severe weather conditions, was a little better than the average job with regard to labor turnover. This was unquestionably due to an adequate supply of common labor in a populous district where there was little emergency call for labor. Sparrows Point, on the other hand, with much better transportation conditions and better weather, but with an extremely deficient labor market, both as to quantity and quality, produced an exceptionally poor record. The laborers obtained on this job (with the exception of two gangs aggregating 264 picked men who were shipped to the job from Boston direct) were obtained through the Government employment service. Addresses on the employment cards showed that they came from six foreign nations and all but eight of the states of the Union. There is no reason to suppose that any other condition would have obtained had this job been on a lump-sum basis instead of the cost-plus which prevailed.

Influenza in Families Made Men Quit

Less than 19% of the men taken to the job from Boston had quit at the end of the first month of employment, as compared with 93% of the total laborers hired on the job. Even this 19% was higher than would normally have been the case, because a considerable number of men left for home on account of the influenza epidemic in Boston, which affected many of their families.

In tabular form the experience of the Aberthaw Construction Co. on these two jobs may be set down as follows:

Job	Total Number Hired	Men at Employment Peak	Ratio	Per Cent. Quit in— Not Over One Week	Not Over One Month
Squantum	10,300	4,200	2.48	29.6	49.8
Sparrows Point	5,245	836	6.27	67.9	88.3

Job	Total Laborers Hired	Laborers on Day of Peak	Ratio	Per Cent. Quit in— Not Over One Week	Not Over One Month
Squantum	6,219	2,688	2 31	31.0	54 8
Sparrows Point	3,017	334	9 03	77.0	93 0

It must not be imagined that these employment figures at Sparrows Point were in any degree due to neglect or lack of adequate supervision. The superintendence, office men and foremen, all were the pick of the organization, and no effort was spared to make the work go smoothly. But the men available were simply "not there." The superintendent estimated the general average efficiency of the men on the job at less than 40%, as compared with 80% for the average on a good pre-war contract, both based on the observed qualities of the best men on the work.

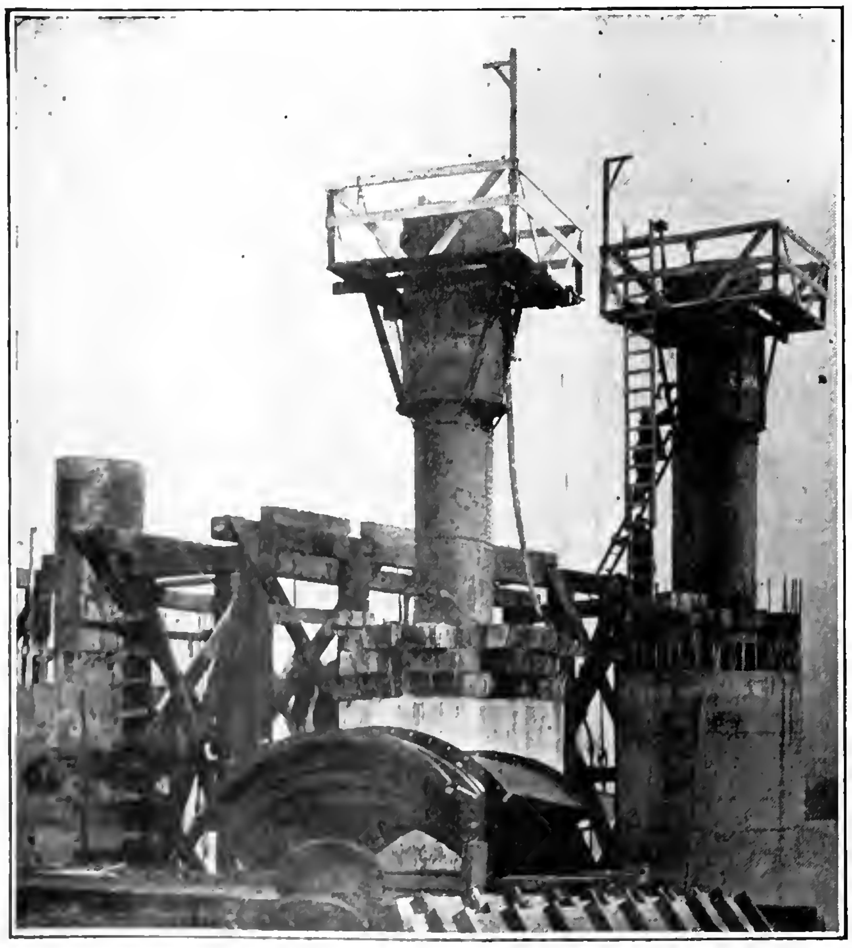
On the basis of an analysis which is as yet incomplete, no marked difference is shown in the percentage of men quitting, whether they are single or married. The question of family responsibility seems to have had little effect, probably because there was always a superabundance of work of one sort or another to which a man could turn any time he had a grouch or felt inclined to wander.

The problem is a very acute one, which will well repay the closest attention and most careful investigation of all employment managers, in hopes of finding some means of overcoming the evil of having constantly to train new men to a job for which an adequate number of men had already been trained. It is a problem which is never so prominent in times when labor is plentiful and jobs are relatively scarce, but it has such a large bearing on costs that anything which can be done to ameliorate the condition will be highly welcome. Once the main causes of dissatisfaction are localized and the proper remedy applied, there should follow quickly a more stable labor condition, with consequent benefit both in costs and in time of construction. This would help everybody alike, laborer, contractor, and owner, but the task of finding the answer is peculiarly one for the contractor alone.

Pneumatic Caissons Sunk Through Moving Ground

Constant Movement of the Earth Necessitates Suspension of Tower Foundation Piers From Overhead Timber Frames

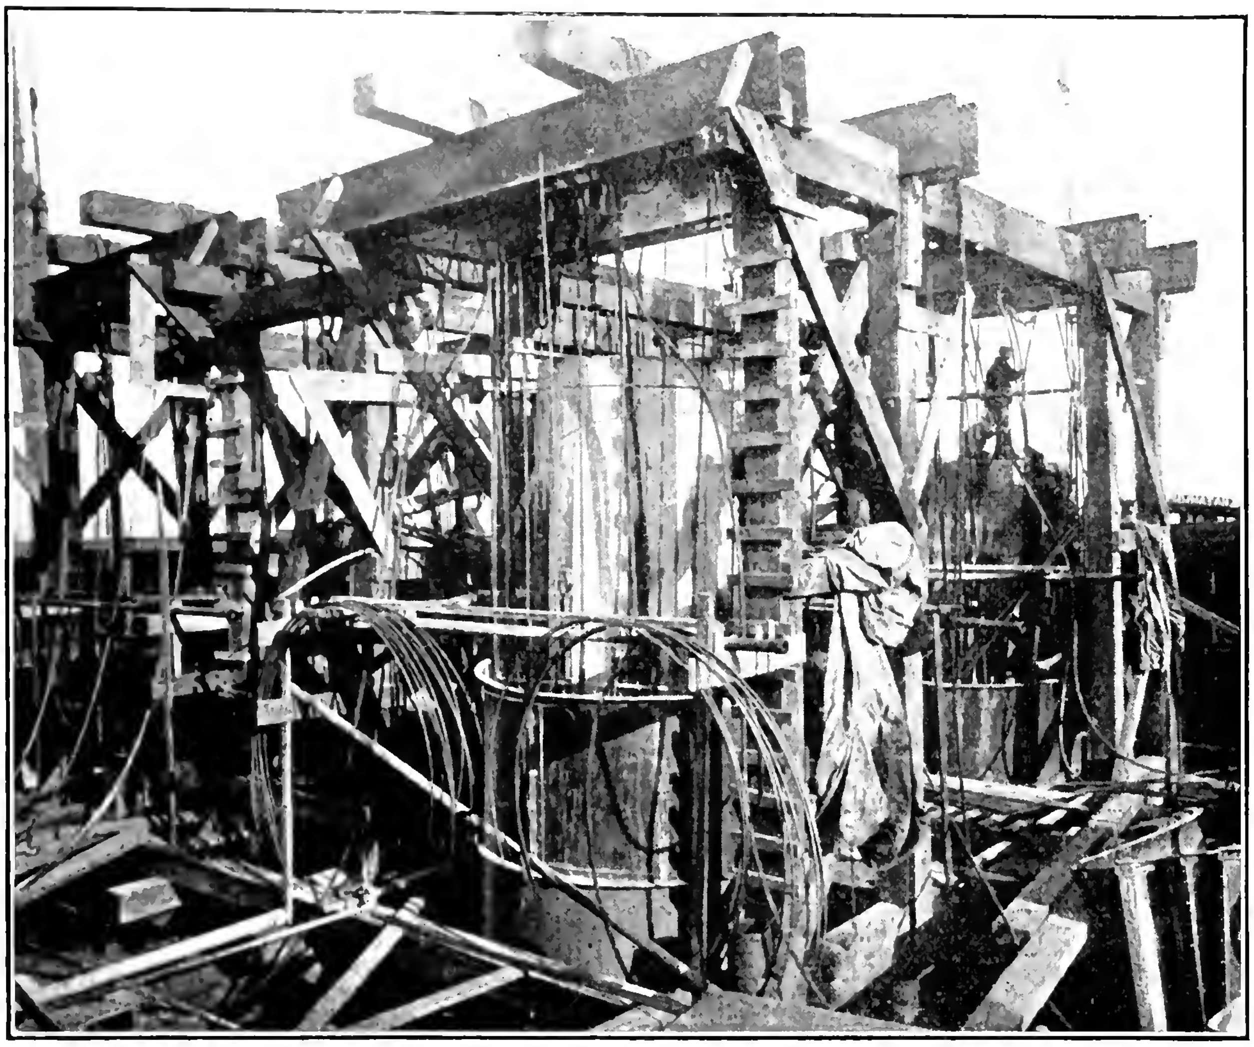
PECULIAR ground conditions in the foundations of the new hoisting tower being constructed near Baltimore for the Consolidated Power Co. forced the contractor to face the problem of sinking pneumatic caissons in such a way that allowance could be made for possible movement of the ground through which they were to be lowered. The solution finally adopted required the construction of an overhead timber frame large enough to support four caissons, one at each corner of a rectangle, from the top of which wire cables in pairs were connected with the bottom of the caissons. These



PNEUMATIC CAISSONS SUNK THROUGH SHIFTING GROUND TO SOLID BEARING

cables were then adjusted as desired during the sinking in order to keep the caissons tilted at the proper angle to allow for the effect of movement in the upper layers of earth. The caissons were sunk by their own weight until solid ground was reached, and from that point carried down about 20 ft. to hard bottom 68 ft. below water level.

The Westport station of the Consolidated Gas, Electric Light & Power Co. is located about 200 ft. from the bank of the Patapsco River, near Baltimore, Md., and the space between the power house and the river is used for the storage of coal brought up the river in barges and unloaded by a tower hoist, which is connected with the power house by a steel bridge. A 1000-ft. cableway extends from the bridge over the storage space, so that coal may either be carried directly to the bunkers in the power house or transferred to the cableway and deposited in the storage pile. The cableway is used, also, to remove coal from the storage pile when it is required to supply the power house.



FOUR PAIRS OF WIRE CABLES SUPPORT EACH CAISSON

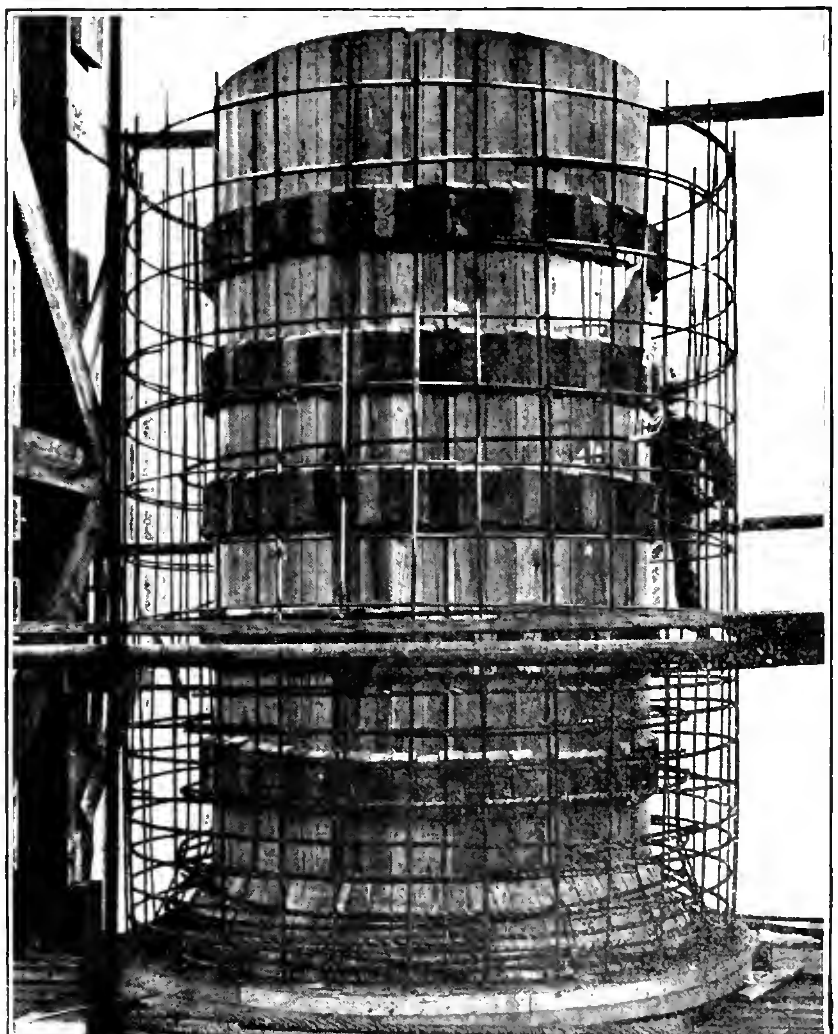
New Hoisting Tower—Last autumn the power company decided to add a second hoisting tower and a bridge, for handling coal. The company expected that it would be difficult to build a foundation for the tower, however, because the weight of the coal stored between the power house and the waterfront had started a movement of the ground toward the river which had been sufficient to throw the discharge tunnels from the power house badly out of line. Accordingly, the Foundation Co., of New York, was engaged to design and construct the necessary piers.

Borings showed that, under about 50 ft. of soft material, there was a stratum of compact sand. It was evidently necessary to sink the foundation piers far enough into this hard stratum to permit them to withstand the flow of the soft material above.

The design finally adopted consisted of four cylindrical piers, 10 ft. in diameter, centered at the corners of a 24 x 25-ft. rectangle. These piers were built with concrete walls, 18 in. thick, reinforced as indicated in one of the photographs, and were sunk by their own weight until they reached solid ground. Air was then applied, and the rest of the sinking was done by the usual pneumatic method. The piers were carried down about 20 ft. to hard bottom, making the total depth 68 ft. below water level.

Contractor's Problem—During the first stages of the operation the contractor was faced by the problem not only of keeping the caissons from sinking too rapidly, but also of holding them in alignment until they were solidly grounded. Four lines of piles were driven at right angles to the river; that is, parallel to the direction of movement of the ground. These piles were capped with 12 x 12-in. timbers and pairs of 24-in. 80-lb. I-beams laid across from one line to the next over each of the four caissons.

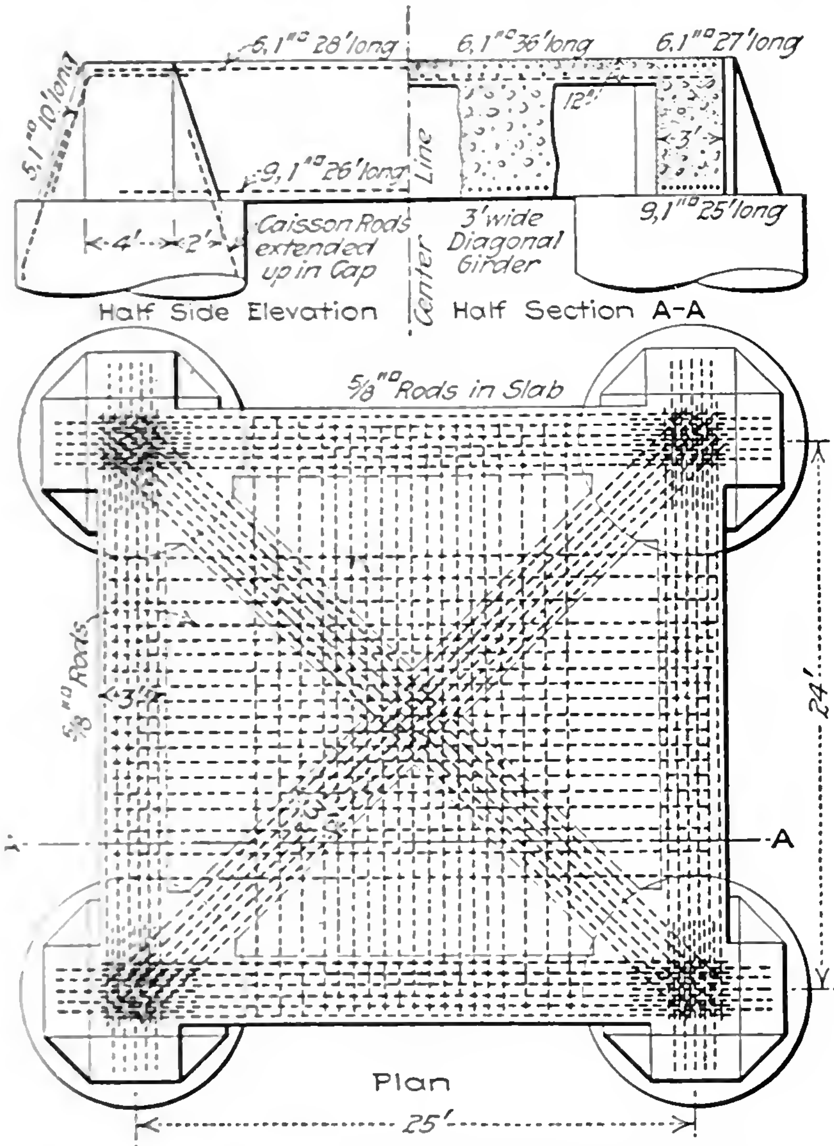
Each caisson was suspended from these I-beams by four pairs of wire cables attached to the cutting edge and extending up through the walls as they were con-



INSIDE FORMS PROVIDE KEYS FOR BONDING

creted. Each cable passed up between the pair of I-beams, made a half turn over an oak block, and was fastened to itself with three ordinary clips. One cable in each pair actually supported the load while the companion cable was held in reserve for safety.

In order that the cutting edge might be in correct position when it reached solid bottom, it was necessary to counteract the movement of the soil, by sinking the caisson out of plumb. The caisson was kept at this



REINFORCED-CONCRETE CAP FOR PIERS, BUILT OF SLAB AND BEAMS

angle by adjustment of the supporting cables. When it was necessary to throw the caissons further out of plumb, the cables on the river side were slacked off, throwing most of the load to the cables on the power-house side and causing the caisson to tilt accordingly.

It was the contractor's original intention to have each cable pass through pairs of blocks, so that it could be more easily adjusted, but as these blocks were delayed in transit, the lowering was done merely by loosening the clamps and allowing the cable to slip by itself. The safety cable in each pair was slacked off first the proper amount, and the clamps were tightened so that the motion of the caisson would be stopped at the proper point when the supporting cables were loosened.

After the caisson had been sunk 20 or 30 ft. it was necessary to shore against the side of the power house to hold it in the proper inclined position. When the cutting edge had been grounded securely, however, these shores were removed and the caisson was allowed to right itself.

After all four piers have been completed, they will be tied together at the top by deep concrete girders, which will stiffen them against the movement of the ground. Details of this cap and its reinforcement are shown in the diagram. The caissons are to be filled with a concrete core about 12 ft. thick at the bottom, with sand filling above it.

A. S. Loizeaux, electrical engineer, is in charge of construction for the Consolidated Gas, Electric Light & Power Co., and E. D. Edmonston is general superintendent of the Westport plant. The job was handled by C. B. Kowenhoven, superintendent, and William J. O'Neill, general foreman, under the direction of W. B. Taylor, district manager of the Foundation Company.

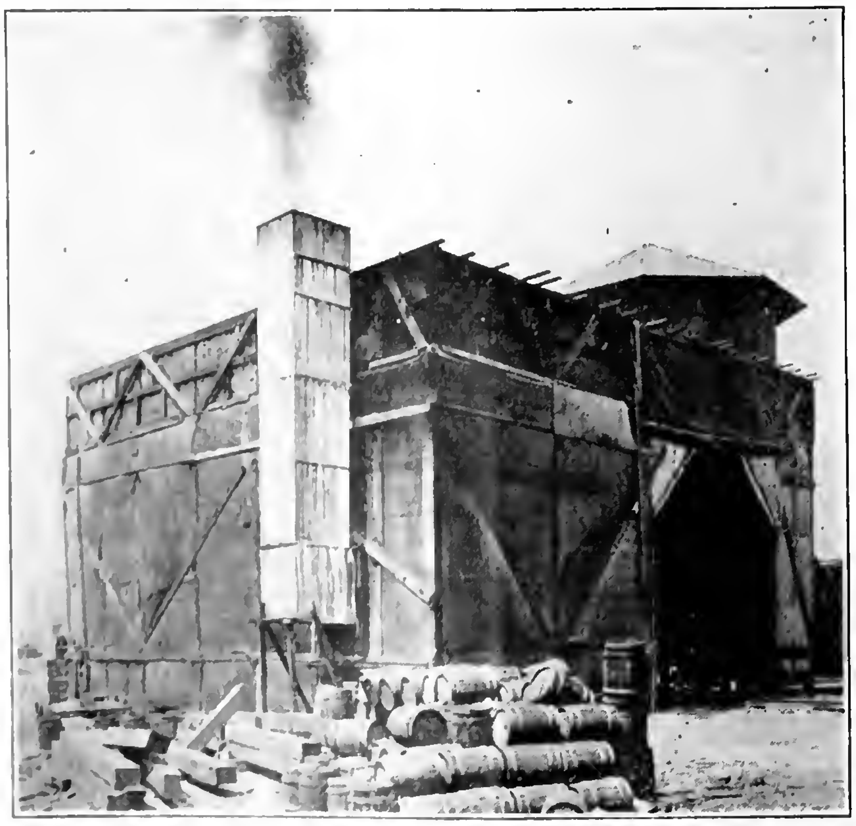
Tests to Free Under Side of Railroad Viaducts From Smoke

Special Arrangement of Ducts, Air Chambers and Fans Promises To Solve Problem of Low Headroom

BY ROBERT H. MOULTON
Chicago

EXPERIMENTS were recently conducted by the engineers of the new Union Station at Chicago to do away with the smoke nuisance created by locomotives under the viaducts. Limited headroom indicated the need for a special arrangement of ducts, air chambers and fans. A test structure was built and adjustments were made of sizes of openings, angles of baffle plates and the like, until the best combination was obtained.

Early in the designing of the station it became apparent that some artificial means would have to be employed to ventilate properly the under side of viaducts at Van Buren St., Jackson Boulevard, Adams St., Monroe St., and the structural portion of Canal St. overhanging the station tracks between Washington and Harrison Sts., a distance of ten blocks. These viaducts pass over depressed tracks and the train-shed of the station, and the use of high platforms made it obvious that smoke and gases could not be permitted to accumulate under these viaducts without seriously inconveniencing passengers and hindering operations of the station. The situation was doubly serious at the Jackson Boulevard and Adams St. viaducts, as these



TEST STRUCTURE—SMOKE ESCAPING AT LEFT

structures practically abut the concourse, and if smoke and gases were permitted to accumulate under these viaducts it would quite likely sift into the concourse and produce an extremely undesirable condition in one of the most used and important spaces in the entire station layout.

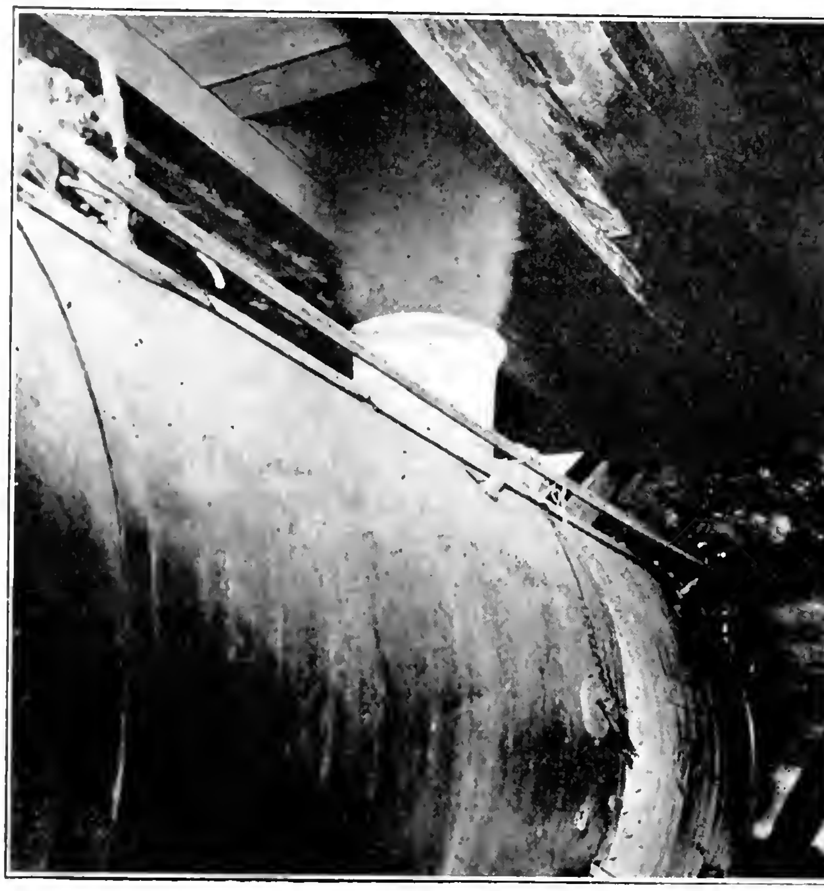
This situation prompted a thorough investigation of other stations, with a view to learning what had been done to relieve such situations. No analogous conditions were found; the situation at the Back Bay Station of the New York, New Haven & Hartford R.R., at Boston partly resembled that in Chicago, although in the main the conditions were dissimilar. At Back Bay the smoke is allowed to remain at or near the ceiling until drawn away through a number of small openings from which a system of ducts leads to ventilating fans. On account of this station having a great deal of headroom the above described method is fairly satisfactory, but it would not suffice at the Chicago Union Station, because if the smoke were handled in the restricted headroom there it would have to be dealt with on a plane only about 6 ft. above the proposed high platforms, or at about the level of a person's head.

Independent Study Solves Problem

Unable to discover anything that might lend assistance to the proper solution of the Chicago Union Station problem, the engineers began an independent and exhaustive study of their needs. After discarding as impracticable schemes which required special devices on locomotives, mechanically operated smoke ducts and one operated by the blast from the locomotives, they decided that the only device that would be entirely satisfactory would be one that could perform its functions entirely independent of the locomotive under all conditions of standing and running, and which also could be installed in a manner that would not require any structural changes in the viaduct design. A design was made of a system of open slots in the ceilings of the viaducts over the track center line. These slots were continuous in length, except where broken by the bottom flange of the viaduct girders, and were first made 30 in. wide at the bottom and 12 in. at the top, the space under the floor of the viaduct and above the ceiling being used as a gas or smoke chamber, and these chambers in turn being connected to a series of flues and ducts leading to ventilating fans.

A complete structure representing a two-track section of Jackson Boulevard was designed and erected, in order that a number of tests could be made as to the volume of smoke to be handled, the necessary air velocities and various other details, such as drainage and cleaning out soot and cinder deposits.

At the first trial of the device it was found that it worked successfully, except that when the locomotive was laboring very hard the smoke and gases had such great velocity that they would slightly overcome the suction pressure of the fan, and this caused a small amount of smoke to escape down through the smoke duct over the next track. It was not desirable to increase the power to overcome this condition, as it was found possible to do, or to construct a separate chamber for each track, on account of the expense of the extra suction flue and additional openings in the web of the viaduct girder much closer to the shearing point. Furthermore, the greater the storage capacity of these chambers the less the fan capacity. After some study



CLOSE VIEW OF ENGINE AND ARRANGEMENT OF SLOTS

of the situation a suction flue was designed with the opening continuous in the form of a slot at the top and a baffle arranged to stop the smoke and gases from passing this point, at the same time guiding them into a slot, the space below the flue being entirely closed. This arrangement operated excellently from the start, and it was not found necessary to make any radical changes throughout the rest of the experiments.

The next question was the adjustment of the angle of the baffle plates which formed the smoke duct. It was found necessary to have a width of about 30 in. at the bottom of the slot in order to catch all of the smoke from the locomotive stack. On the other hand, if the opening at the top of the baffle plates, where the smoke passed into the smoke chamber, was made too narrow, the smoke, due to its high velocity, would flare back. It was desired to make the slot opening into the smoke chamber as small as possible, as it is obvious that with a given velocity through the slot the total slot area would determine the necessary size and power required at the fan. If it were required to take care only of the gases and smoke from the locomotives while standing, or running light, a smoke slot 6 in. wide and an air velocity of 125 to 150 ft. per minute could be used. It was found, however, that to take care of all conditions, particularly an engine working hard, with the drivers slipping, it was necessary to make the smoke slot opening 9 in. and to keep the air velocity at 300 ft. per minute.

The baffle plates in the smoke ducts will be made of cast iron, as they come directly in contact with the locomotive blast. A protection plate of cast iron will be erected on the ceiling of the smoke chamber over the opening in the smoke slot.

The baffle plates will be provided with weep holes to drain the bottom surface of the smoke chamber when necessary. This undoubtedly will be seldom, as in all large experiments the smoke chambers were very dry, because of the large volume of air passing through them, absorbing all moisture and leaving a dry deposit of soot. All cinders were carried away by the fan

and were expelled into the outside atmosphere with the smoke.

While the tests have shown that the smoke chambers are very dry, it is possible that in very cold weather there may be some condensation. This, however, will be taken care of, as explained before, by weep holes in the baffle plates, allowing any moisture to drop to the floor of the track and thus be carried away by the track drains.

Viaduct Divided Into Small Units to Obtain Best Load Conditions

It was first proposed to treat each half of one viaduct as one unit of the system, but as it soon became evident that there was no economy in such a proceeding, it was decided to divide the viaducts into small units, and thus obtain the best load conditions that it is possible to put into effect at the power house.

It is intended to operate the fan motor by remote control switches at some central point, manipulated by some person from the station master's office—in all probability the same attendant that will look after the platform lights and train indicators. Automatic switches for the fan motors were considered, but were eliminated on account of their complications and their cost. The test structure was built under a contract which specified that all of the material was to become the property of the contractor when the structure was dismantled. The total amount of money that was expended on the experiment was $2500.

The engineers believe that the device is practical in every way, and they found, after a series of tests covering a period of three months, that the operation was very satisfactory and all that could be desired. This opinion was shared by outside engineers who observed the working of the device.

Safety Records in Building Construction in San Francisco

To show that safety precautions on building construction need not be costly, the California Industrial Accident Commission has compiled statistics covering work supervised by its safety engineers. An example is made of three large buildings recently completed in San Francisco, on which a particularly good record is reported. These are the California Theater and the Santa Fé and the Southern Pacific Buildings. The 10-story Southern Pacific Building, said to be the largest office structure west of Chicago, cost $1,500,000. On this job the cost of safeguarding 300 workers for a period of 12 months was $3952.50, or $13.15 for each worker employed.

On the 12-story Santa Fé Building, costing $350,000, the safety expense was $1032.35. This covered 175 workers for a period of six months, the cost per worker being $5.89. On the California Theater, which cost $500,000, thirty men were protected for 38 days for a total of $420, of which $240 was spent for nets. These were practically as good as new when the work was finished, and a salvage value of $200 is deducted from the cost of the nets, making the total cost of the safety provisions only $220. On none of these buildings was there loss of life or serious injury above the foundation level. One man was killed during the piledriving on the Southern Pacific Building.

Overhead and Time Cost to Erect Elevated Railway

Nine Hours per Ton Required to Haul, Erect, Rivet and Paint 13,500-Ton Structure—Overhead 30 Per Cent. of Total

By A. P. Roscoe
Ozone Park, New York

It cost nine labor hours per ton and $11 per ton to haul, erect, rivet and paint 13,500 tons of steel elevated-railway structure in New York City in 1916-1918. The precise costs were 9.21 hours and $10.95. Standard methods were employed, but delays of various kinds about doubled the time which would ordinarily have been required for the work. Overhead expenses ran from 19% to 37% of the total cost of the work. Stress was laid on recording overhead, and, in particular, on itemizing the labor hours expended.

Erection operations covered 11,190 ft. of three-track elevated railway, including five stations. The route was along an unpaved street with a two-track overhead-trolley electric railway. Crossing streets were about 700 ft. apart. Traffic was light and the street was only partially built up. Obstacles to erection operations consisted principally of electric trains and trolley cars operating below the structure and of live trolley wires and feeder cables which necessitated special precautions in handling steel.

Unloading and Hauling Steel

All of the steel, 13,394 tons, and the castings, 154 tons, were delivered in the original cars to a storage yard where they were unloaded by a 15-ton steel stiff-leg derrick. Some 640 tons, made up of especially large or heavy members, were hauled to the point of erection on flat-cars and there unloaded by the erection traveler. The remainder, 12,900 tons, was hauled by a fleet of three-ton motor trucks and trailers and was unloaded onto the street by hand. The largest pieces hauled by motor truck were 15-ton 90 x 7-ft. track stringers and 26-ton 63 x 7-ft. cross-girders. The average haul was 2200 ft., and the average piece was handled three times. The hours of labor per ton unloaded and hauled were:

Item	Hours per Ton
Foreman	0.228
Hoisting engineer	0.202
Bridgeman	0.456
Laborers	0.203
Motor truck and driver	0.408
Total	1.497

The money cost of hauling and handling is of importance chiefly because it shows the proportions of overhead expenses. These are divided into general overhead and special overhead, as explained and discussed in a separate summary and discussion of overhead below. The following tabulation gives the exact figures:

Item	Loading and Unloading	Hauling	Total
Direct labor	$0.596	$0.568	$1.164
Insurance	.133	.128	.261
Meneral overhead	246	.234	.480
Special overhead	.269	.015	.284
Total	$1.244	$0.945	$2.189

Erecting Steel—The steel erection included 211 bents, 453 columns and one express and four local stations aggregating 12,665 tons of riveted steel, 546 tons of beam steel and 87 tons of steel footing slabs. The bents

were 50 ft. apart, on an average; each consisted of two columns spaced 26 ft. apart carrying a 6-ft. cross-girder. The columns were made up of one 15-in. I-beam and two 15-in. channels with cover plates where necessary. Six 5-ft. plate girders were framed between the bents and braced laterally and for traction, to carry the three tracks.

At stations, street intersections, surface-railroad turnouts, curves, etc., this standard construction was modified to meet the conditions. Station platforms 500 ft. long consisted of two 3½-ft. plate-girder stringers supported on the cantilever ends of the cross-girders, with bracing and platform beams and a cantilever canopy. There is a mezzanine floor at each end of the station; this consists of shallow plate girders and I-beams suspended from the girders by double-angle hangers. The tracks are 13 ft. on centers except at the island express station, where they are 27 ft. 4 in. on centers.

A gantry traveler rolling on trucks on the center track stringers erected the steel. This traveler consisted of a timber platform, an 18 x 18-in. timber mast with a 16-ft. bull wheel, a 16 x 16-in. timber A-frame supporting the mast, two 14 x 16-in. timber backstays, and an 80-ft. lattice steel boom rated at 25 tons at 25-ft. radius and at 12 tons with flat boom. Hoisting was done with an 8 x 12-in. steam hoist equipped with swing gear.

The overall dimensions of the traveler were: Length 52 ft., width at front A-frame 32 ft., height from top of stringer to top of mast 47 ft. When raising steel the traveler was dogged down to the center track stringers in the rear and to one outside track stringer at each end of the front outriggers. It was hauled ahead by a set of falls attached to the cross-girder ahead and operated from the traveler winch head.

Erection of Steel

Steel was usually raised from the street surface, occasionally from motor trucks or flat-cars. The main steel was erected with the traveler falls. Cross-frames and canopy steel were erected with the boom runner line. Laterals were raised by the traveler and put in place by the fitting-up gang. At eight points the span length exceeded the reach of the boom, these spans being 80, 90, 88, 100, 85 and 90 ft. The columns and cross-girders at the 80- and 85-ft. spans were erected by the traveler boom by outhauling with a runner line reeved through a block anchored ahead of the bent being erected. The cross-girders for the longer spans were set by a steel ginpole using the traveler falls and topping lift to supply power. The heaviest piece raised by the boom was a 30-ton cross-girder.

In standard construction the average weights of pieces were as follows: Columns, two tons; cross-girders between stations, five tons; cross-girders in stations, 10 tons; track stringers, six tons; platform stringers, 3½ tons; through girders over mezzanines, 19 tons. The heaviest piece was a through girder of 91½ ft. span, weighing 36.7 tons. The longest piece was a 110-ft. platform girder weighing 12½ tons. The average panel weight was 62.9 tons and the average weight per foot of structure was 1.18 tons, or 2360 pounds.

The erection gang contained 19 men, as follows: Raising main steel, one foreman, one engineer, six bridgemen, two apprentices and one flagman; fitting up small steel, one pusher, five bridgemen and two apprentices. The hours of labor per ton of steel erected were:

Item	Hours per Ton
Foreman	0.162
Pusher	0.143
Engineer	0.158
Bridgeman	1.381
Apprentice	0.495
Team	0.091
Laborer	0.134
Total	2.564

The money cost, based on 13,300 tons, was as follows:

Item	Per Ton
Direct labor	$1.635
Insurance	.367
General overhead	.684
Special overhead	.481
Total	$3.167

Field Riveting—The total tonnage riveted was 13,211 tons, of which 546 tons were beam steel. A total of 265,800 rivets was driven by air hammers. A gasoline-driven compressor on the street supplied air to an average of 5 four-man gangs. No scaffolds were required except at column brackets. All rivets were ⅞-in. button-head, except in columns and canopies, where ¾-in. rivets were used. Labor time costs include blacksmith work, operating the compressor, laying and removing the air pipe, reaming, placing scaffolds and riveting, and in hours per ton were as follows:

Item	Hours per Ton
Foreman or pusher	0.119
Engineer	0.154
Bridgeman	2.187
Apprentice	0.245
Blacksmith	0.071
Blacksmith helper	0.041
Total	2.817

The average number of rivets driven per gang per day was 294. The cost per ton and also per 10 rivets driven was as follows:

Item	Per Ton	Per Ten Rivets
Direct labor	$1.925	$0.958
Insurance	.433	.215
General overhead	.802	.399
Special overhead	.208	.103
Totals	$3.368	$1.675

Painting—A total of 13,211 tons of steel was painted. All structural steel had received one coat of red lead before leaving the shop. After erection, all rusted or otherwise damaged portions of the shop coat were scraped and repainted. The shop coat was in good condition except for three subsections, comprising 3700 tons, which had been stored exposed to the weather for more than a year. Here the shop coat was badly damaged and required extensive renewal. The first field coat was black, the pigment being 50% red lead, 25% lampblack and 25% magnesium silicate and silica. The second field coat was olive green in color, the pigment being red lead 10%, lampblack 3%, magnesium silicate 10%, yellow ocher 67% and chrome green 10%. The vehicle for both field coats was raw linseed oil, with 5% and 6% of driers, respectively. All painting was done with flat brushes. The labor costs in hours per ton were as follows:

Coat	Hours per Ton Foreman	Hours per Ton Painters
Shop coat renewal	0.109	0.850
First field coat	0.111	0.644
Second field coat	0.078	0.540
First and second field coat	0.189	0.184
All painting	0.298	2.034

The money costs, based on 13,211 tons of steel, were

as shown in the table which is reproduced herewith:

Item	Cost per Ton: Renewal of Shop Coat	First Field Coat	Second Field Coat	All Painting
Direct labor	$0.375	$0.304	$0.250	$0.929
Insurance	.071	.058	.047	.176
Material	.328	.199	.176	.703
General overhead	.151	.125	.102	.378
Special overhead	.016	.014	.011	.041
Total	$0.941	$0.700	$0.586	$2.227

Overhead Expenses—Separation was made of overhead expenses, as shown by the tabulations, into general and special overhead. Included in general overhead are: Bond premium, interest on invested capital, lost interest on retained percentages, proportionate part of main-office salaries and expenses, field supervision, field-office rent and expenses, rent of yards, construction shanties, and legal expenses. Special overhead includes tools and supplies, plant depreciation and repairs, watchman, water boy, etc., particular to the individual operation.

The total of the general overhead items was distributed among the items of the work, first in proportion to the money value of the work and, second, in the ratio of the direct labor cost on each item. The amount charged as general overhead on any item of work was the mean of these two figures. The percentages of overhead in the various items of erection work are given by the following tabulation:

Item	Direct Labor	Labor and Material	Total
Unloading and hauling	65.5	53.6	34.8
Erecting	71.2	58.3	36.8
Riveting	52.5	42.8	30.0
Painting	45.1	23.2	18.8
Total	59.5	44.2	30.7

The cost of the steel itself f.o.b. yard is not included in "Material" in the above tabulation. If the cost of the steel is included at $40 a ton the percentage of overhead on labor insurance and material would be seven per cent.

Irrigation for Soldiers' Lands in Kansas

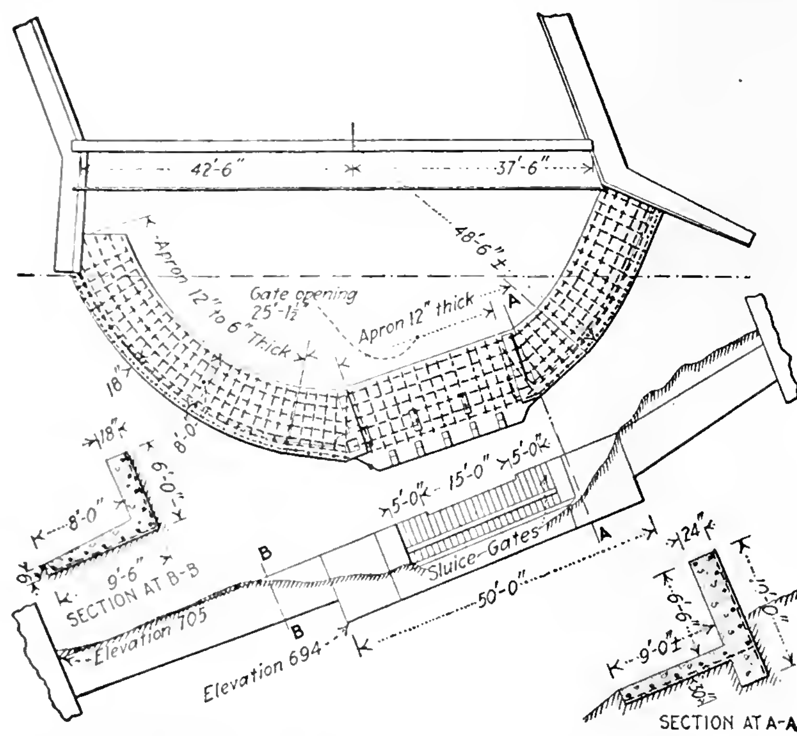
Study of the area of land irrigated and possible of irrigation in western Kansas has been made as part of an investigation concerning homes for returning soldiers. Rainfall in Kansas averages 30 to 40 in. per year in the eastern third of the state, 20 to 30 in the middle and less than 20 in. in the western third. Reports from 17 of 39 counties in the last named section showed 73,626 acres under irrigation by both ditch and pump methods, or an average of 4331 acres per county, exclusive of truck gardens. Applying this figure to the other counties and including the land which is irrigated only occasionally, the total area under irrigation is estimated at about 100,000 acres. Estimates of acreage possible of irrigation totaled 1,404,480 acres for 18 counties, or over 60,000 per county. The estimate of such land for the entire section is 1,876,080 acres. Inquiry made concerning supplemental irrigation of crops, employed only during periods when rainfall is abnormally light, showed good results from this practice.

These investigations were made by J. B. Marcellus, drainage and irrigation engineer for the division of college extension at the Kansas State Agricultural College, Manhattan.

Balanced Automatic Sluice Gate for Park Dam

In Central Spillway of Concrete Dam the Movable Timber Section Drops When Flood Height Tops Main Crest

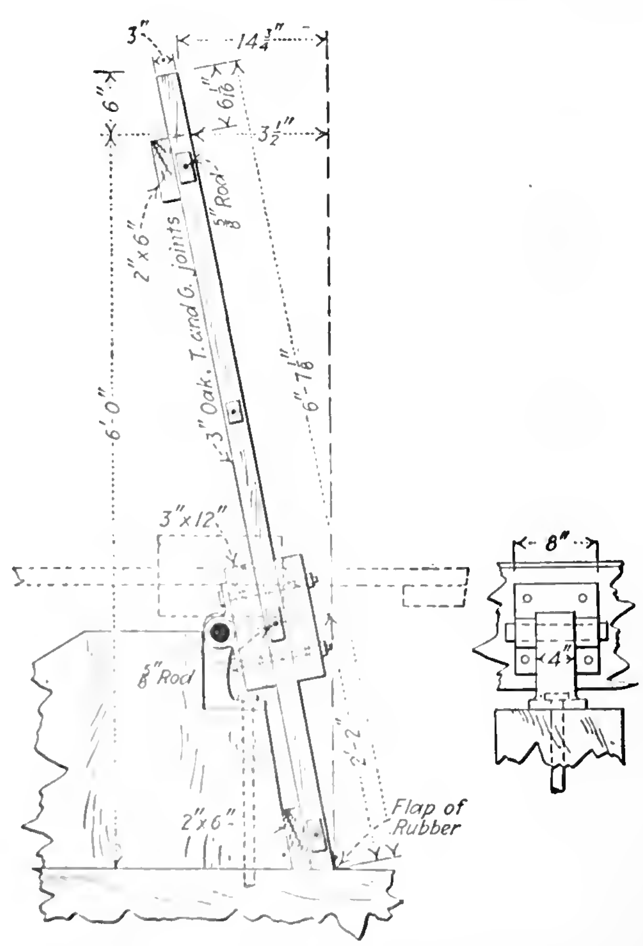
IN ORDER to provide spillway space during floods and reduce the deposition of sediment in the pool, an automatic sluice gate was designed and built for a dam in Harmon Park, Lebanon, Ohio. The dam itself is roughly semi-circular in plan, as shown in the drawing,



PARK DAM WITH MIDDLE AUTOMATIC SLUICE GATE

and consists of an L-shaped concrete main section with a central spillway section in which is placed the automatic wooden sluice gate.

This sluice gate, as shown in the detailed drawing, is in effect a shutter 25 ft. long and 6½ ft. deep, made

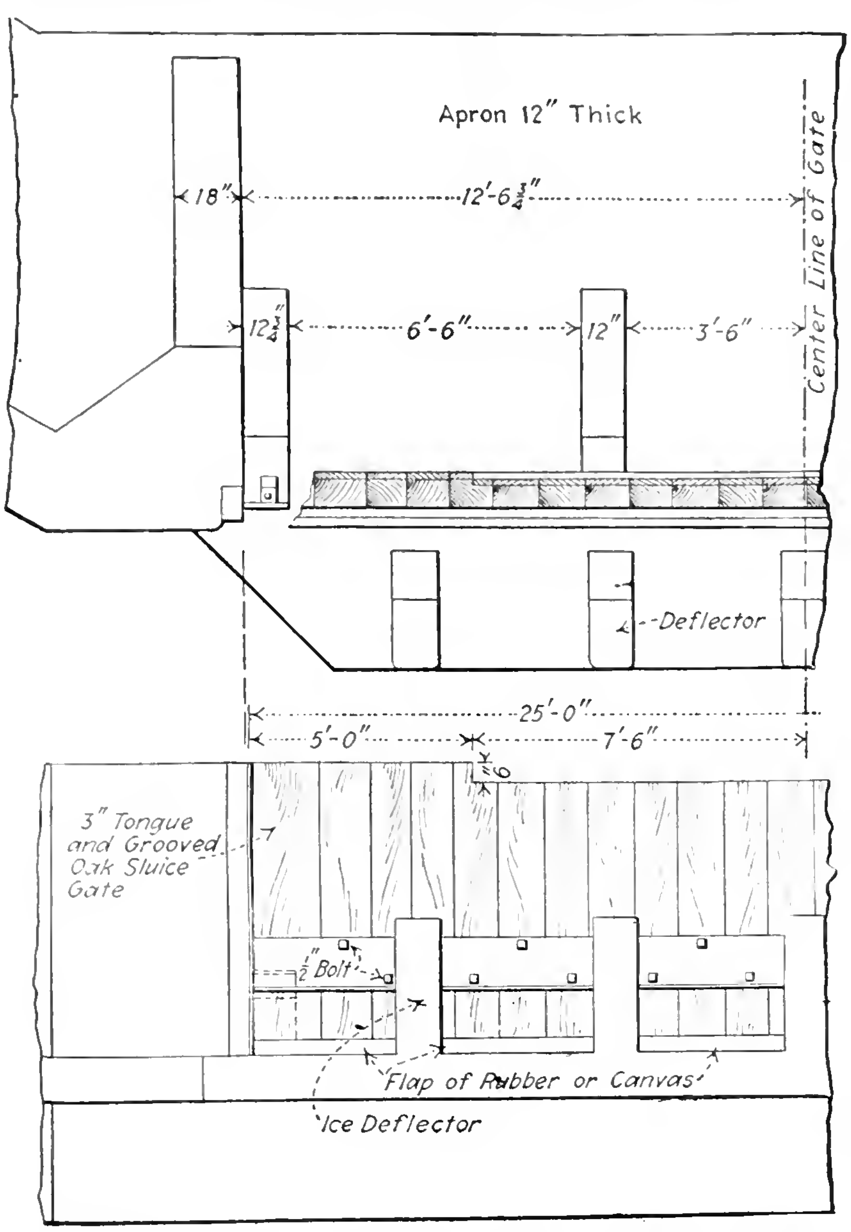


END ELEVATION OF SLUICE GATE

up of 3-in. tongue-and-groove oak plank placed vertically on a transverse 3 x 6-in. sill. This sill, which is at the lower third point of the gate, bears against hinges on concrete counterforts raised from the concrete apron

AUTOMATIC SLUICE GATE AT LEBANON, OHIO, WITH FLOOD JUST PASSING OVER ITS FULL HEIGHT

of the spillway. When the water reaches such a height that the overturning moment is greater than the resisting moment of the water head, the gate turns until it becomes horizontal and allows the flood to pass over.



ELEVATION, SOUTH HALF, LOOKING DOWNSTREAM

Small deflectors of concrete in front of the sluice gate are made of concrete walls integral with the concrete base of the apron.

The dam has now been in place about 18 months and has passed one spring freshet successfully. It was designed by Frank A. Bone & Son of Cincinnati, Ohio.

Trade-Waste Treatment Studies in Wisconsin

Wide Range of Investigations Made to Help Lessen Water Pollution—Treatment Methods—Test Plant at Milwaukee

By E. J. Tully
State Sanitary Engineer, Madison, Wis.

THE Division of Sanitary Engineering of the Wisconsin State Board of Health has devoted particular attention for some time to the prevention of water pollution by industrial wastes. Investigations have been conducted in every section of the state. The aim in selecting the system of treatment has been to combine effectiveness with simplicity of construction, reasonableness in cost and simplicity of operation, to eliminate technical supervision and to include recovery or partial recovery of waste products, as this is the ideal solution, when feasible. These investigations have included examination and small-scale experimental studies of creamery, cheese-factory, casein, canning-plant, gas-plant, brewery, tannery, rendering, glue, woolen, starch, iron and steel plant, paper and pulp mill, both sulphite and sulphate, coke-oven, chemical and dye, and explosives-plant wastes. In every instance, local sanitary requirements are the prime factors in deciding on the degree of treatment. The main purpose is to effect satisfactory reduction—depending on circumstances—in concentration of organic matter, and thereby to produce an effluent of such character that disposal by dilution may be satisfactorily accomplished, utilizing as fully as conditions permit the dilution method of purification, since it is our opinion that if a water course can receive and satisfactorily dispose of partially treated rather than completely purified wastes, without offense or detriment to riparian owners, it would be unwise and uneconomical not to take advantage of the opportunity to make the most reasonable use of the purification factors of dilution.

It has been found desirable to outline in blueprint form, after local investigation, the type of treatment unit or system believed to be adequate to accomplish the degree of purification deemed sufficient to meet local sanitary requirements. Instructions are given in constructional features and operation and care of the system. The necessity for supervision is emphasized. A wooden plank cover for the unit is specified. Considerable attention has been devoted to creamery and cheese-factory wastes, and wastes of canning factories, gas plants, tanneries and paper mills.

The procedure in the treatment of creamery and cheese-factory wastes, as these are comparable in character, includes discharge of cooling and boiler waters directly, where this is feasible; disposal of chemical wastes in excavation, and treatment of industrial waste proper, and of sewage, in case a public sewer system is not available, in a combination unit comprising two or three retention chambers. The first one contains a liming trough below the inlet or a section filled with crushed limestone, and the last is followed by a contact coke continuous chamber, and a gravel sand filtration chamber. A filtration trench is sometimes substituted for the type of filter. The disposal of casein waste is accomplished in somewhat similar manner, neutralization of the acid waste being effected by soda-ash before sedimentation, which is followed by gravel and sand

filtration. Disposal of these wastes by subsurface filtration, where the geological formation is gravel or sand, is resorted to, after preliminary treatment, when dilution is not feasible.

The canning industry is quite an important one. Wastes from this type of industry include, besides cooling waters, sewage and industrial waste proper, comprising pea and corn washings, plant washings and silage juice. Effective disposition includes direct discharge of cooling waters, discharge of domestic sewage by connection with the public sewer system, when available, conveying, after coarse screening, corn, pea, and plant washings, silage juice effluent, and sewage, when necessary, to a single point, and subjecting them to sedimentation in a three-section settling basin, and straining in a roughing filter, contact or direct, according to conditions. Preliminary treatment of silage juice is effected in a small three-section unit combining filtration through crushed limestone to accomplish partial neutralization, coke contact filtration and gravel filtration. In some instances, preliminary treatment in a single unit includes sedimentation after neutralization with soda-ash, applied from a barrel equipped with a faucet, coke contact filtration and gravel filtration. When a water course is not available or is relatively distant and a gravel formation is at hand, disposal by natural filtration in a series of excavations, after preliminary treatment, is an indicated procedure. Recovery of waste products and substances of fertilizing value is accomplished.

Tannery waste, because of its volume, usually requires large-scale treatment, the plan of disposal including differential screening in a long conduit prior to sedimentation in a two-section unit, each section comprising two chambers, and coke contact or direct filtration. Recovery of byproducts, hair and products of fertilizing value, is effected.

The plan of treating gas-plant waste consists of discharge into concrete tar-retention chambers and treatment of the effluent in a unit composed of four chambers, the first a sedimentation section containing a liming trough below the inlet, the two following chambers functioning as coke contact filters, the fourth and last a gravel-sand filter. The heavy tars recovered have been used for road work.

The relatively great volume of paper-mill wastes presents an element of difficulty in attempting to deal satisfactorily with this type of discharge. The procedure as to disposal includes the recovery of byproducts, woody suspended matter and pulp, and comprises differential screening for removal of woody suspended matters; the final screen or save-all being 80-mesh, the discharge from the screen passing into a box of adequate area containing a perforated flooring over which is laid o double layer of rope netting, which functions as a strainer or filter; sedimentation and pressing of mineral suspended material, reduction being effected before pressing by admixture with sewage, if necessary; and coke filtration, either contact or direct, or a combination of both, depending upon conditions, of "blow liquor," liquid waste proper.

Coke byproduct and chemical wastes are treated by a plan comprising chemical application, sedimentation, and aëration by discharge over shallow beds of stone, or filtration through a system comprising contact or direct coke beds, or both, and a gravel-sand bed.

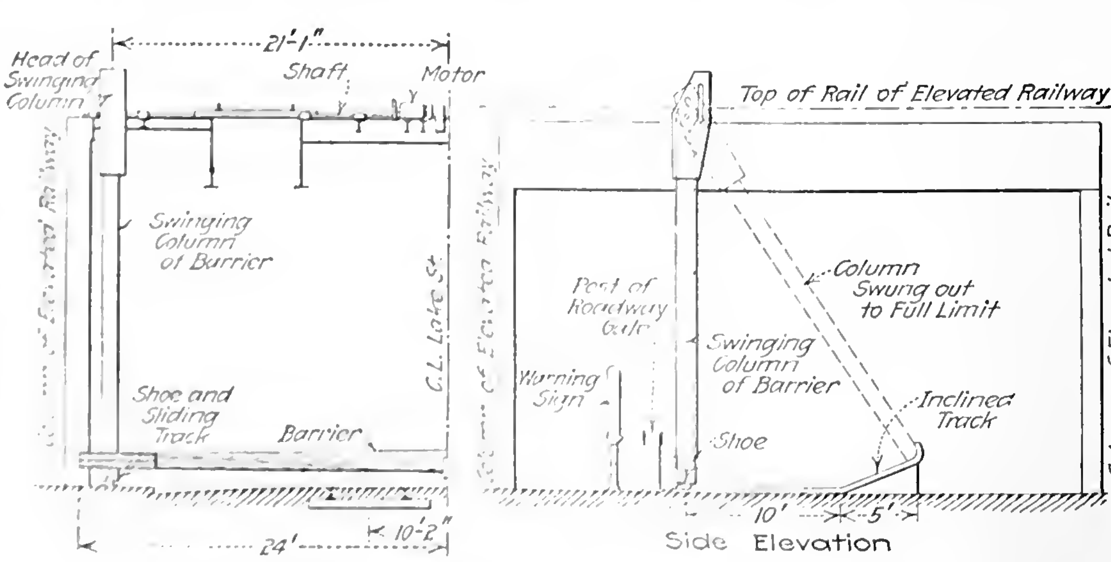
The Division of Sanitary Engineering has designed a fairly large experimental plant of wooden construction to treat, at a Milwaukee plant, chemical discharges, ammonia liquors, coke quenching waters, etc. The system comprises a sedimentation basin 15 x 4 ft. in plan and 5 ft. deep, a coke contact filter, 6 x 6 x 5 ft. deep, using 1-in. medium; a coke filter 6 x 6 x 5 ft. deep, using coke breeze as the upper layer of the filtering medium, distribution being effected by a wooden trough equipped with lateral, triangular boards, 6 in. at base and cut to a point at the end, and attached at openings of the trough; and a gravel-course sand filter, 6 x 6 ft. in plan, containing about 3 ft. of sand medium supported by coarse aggregate, with distribution as in a coke filter. The system is now in operation, and it is intended to experiment with the raw waste and to try coagulants and admixtures with sewage. A progress report will be submitted soon.

Yielding Barriers Close Roads at Drawbridges

Impact of Vehicles Absorbed by Traveling Gate to Stop Motor Trucks, and by Cables to Stop Automobiles

ESSENTIALLY different types of barriers to close the approaches to open drawbridges are represented by recent installations in Chicago and at Salem, Mass. The former, which is designed to stop the heaviest vehicles, consists of a rigid pole carried on traveling supports which move backward against sliding frictional resistance. The latter is designed only to stop automobiles, and is composed to cables attached to the pistons of oil-filled cylinders which form hydraulic brakes. Two other yielding barriers, both of the flexible or deflecting type, were described in *Engineering News-Record* of May 23, 1918, p. 1008.

For the protection of vehicles on the approaches to the Lake St. bascule bridge in Chicago there are provided yielding barriers which are designed to stop even electric cars and heavy motor trucks that may disregard the warning signals. This is a double-deck bridge, with an elevated railway on the upper deck; when it is open the roadway on either approach ends at the edge of



RIGID BARRIER AT LAKE STREET BRIDGE, CHICAGO, SWINGS BACK AGAINST FRICTIONAL RESISTANCE WHEN STRUCK

a large open tailpit 45 ft. deep, so that it was necessary to provide some sure method of stopping vehicles approaching out of control. The barrier is placed 8 ft. beyond the usual swinging-arm gate, leaving a 20-ft. space between the barrier and the pit.

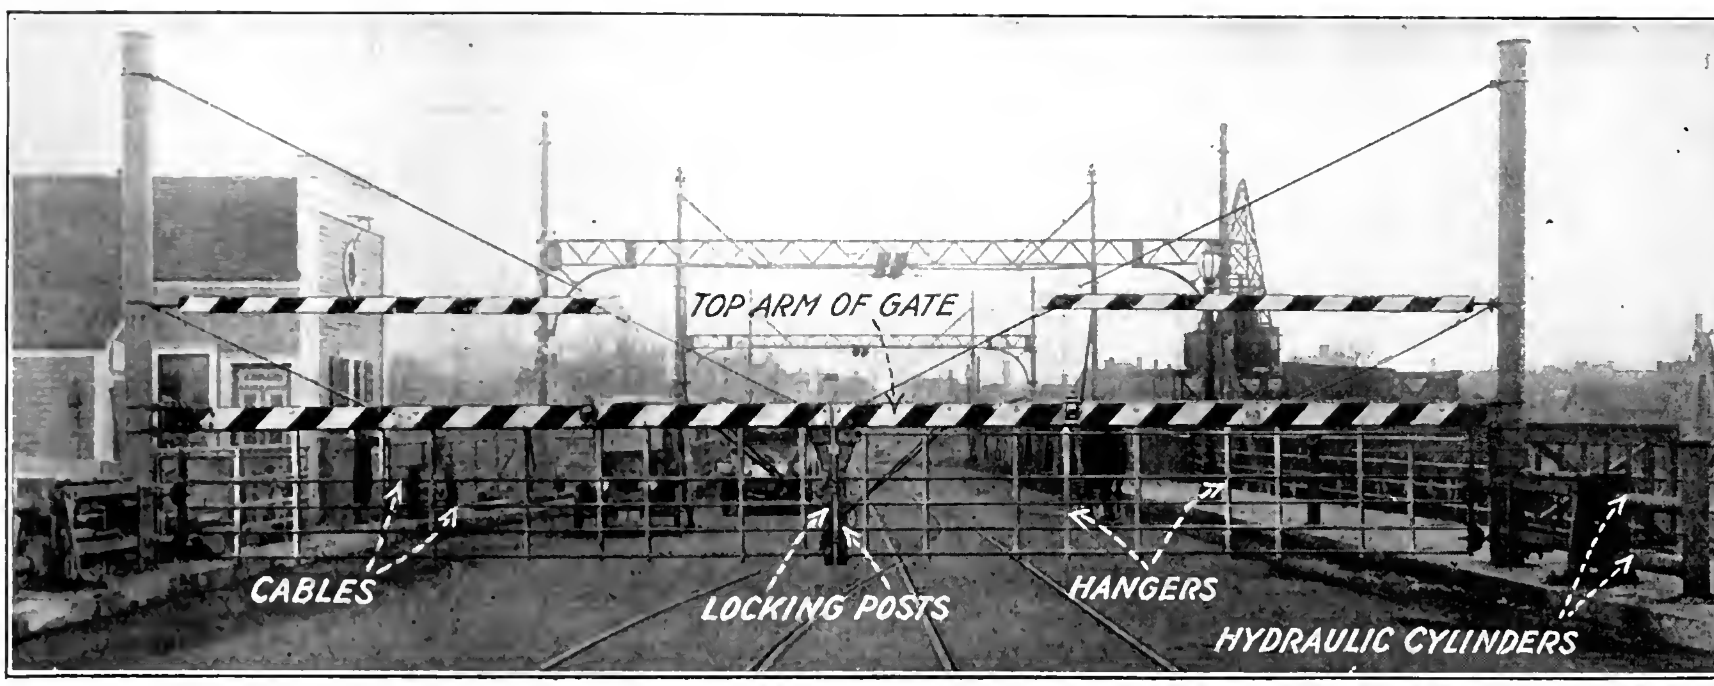
The barrier itself is a Douglas fir stick about 42 ft. long, turned to a diameter of 16 in. at the middle and having ends 10 in. square fitted to steel forks or guides. Truss rods on each side add rigidity to the timber. The forked ends engage vertical columns of 12-in. pipe which are seated on wheels and sliding shoes at the curb line and have their upper ends pivoted to a shaft carried by the girder framing of the elevated-railway approach. Each end of the barrier is attached to two ½-in. cables wound upon a drum in the structural steel head of the column, which drum also carries two similar cables for a cylindrical cast-iron counter-weight sliding inside the column. A 5-hp. motor operates the shaft and cable mechanism. The timber is housed normally beneath the girders of the elevated railway; when lowered, its center line is about 2 ft. above the roadway.

While the column has a rotating motion around the shaft it is not journaled to it, the shaft lying in a slot which permits vertical movement of the column. The foot of the column has a 10-in. wheel resting on track rails parallel with the curb, and outside of the wheel are shoes sliding on flat track plates so as to afford frictional resistance. The rails and the track plates are inclined, as shown in the drawing. When the barrier is struck the columns roll back on the wheels until the shoes engage the track plates and slide upon them. The steep incline of the end portions of these adds further resistance, and an end stop limits the total travel to 15 ft., with a vertical rise of about 2 ft. in that distance.

As a test, an old eight-ton electric car with front end reinforced against the shock was run against the barrier at a speed of 12 miles per hour, carrying the barrier to the full limit of its travel without injury to the barrier or the car. No unintentional test due to careless driving has occurred. To provide against street cars being held on the bridge by the lowering of the barriers, there is an automatic interlocking device which prevents operation of the barriers or the bridge while a car is between the gates.

This yielding barrier was designed by F. H. Avery, engineer of bridge construction and repairs, Department of Public Works, Chicago, who superintended the plans and construction under the direction of John Ericson, city engineer, and Thomas G. Pihlfeldt, engineer of bridges. The contractor was S. P. Harding.

Protection of automobiles on the approaches to the Essex drawbridge between Salem and Beverly, Mass., is afforded by flexible yielding barriers which are designed to stop light vehicles and which it is thought will check heavy trucks to such an extent that they can be stopped in the 75-ft. distance between the barrier and the draw opening. While a street car or heavy motor truck at high speed would probably break through the barriers, it was considered best not to attempt to make them strong enough to stop a truck, while the stopping of street cars was considered to be a matter for the electric-railway company.



FLEXIBLE BARRIER OF CABLES YIELDS UNDER IMPACT BY PULLING OUT PISTONS IN HYDRAULIC CYLINDERS

Each barrier is composed of two horizontally swinging gates or leaves which meet at the center of the roadway. Each leaf consists of a combined steel and wood arm placed 5 ft. above the roadway and carrying hangers through which are led four ⅝-in. wire cables 10 in. apart. At the outer end of each leaf the cables are attached to a vertical member hung from the top arm but free to disengage from it. When the gates are closed the locking mechanism on these members is engaged by levers, so that the cables form a continuous structure across the roadway.

At the hinged end of the leaf each pair of cables is looped around a stirrup to which is attached a ¾-in. cable passing over a horizontal guide sheave on the gate post and attached to the rod of a piston in an oil-filled cylinder. The two cylinders on each side are mounted in a frame placed parallel with the curb. Should the gate be struck by a vehicle it will yield, the pressure on the gate cables pulling out the four pistons against the resistance of the oil. The top arms are hinged at two points in each leaf and are not connected at the center, so that they are free to follow the curve of the cables without breaking. At the same time the hinges are so supported as to prevent vertical deflection of the arm.

Wrought-iron pipe of 5½-in. inside diameter is used for the cylinders, with a piston diameter $\frac{1}{16}$ in. less. Through the $\frac{1}{32}$-in. annular space the oil escapes as the piston is pulled forward. To prevent excessive pres-

sures and a too sudden stop to a light vehicle moving rapidly, a safety valve provides for escape of a portion of the oil when the pressure reaches 8000 lb., or about 500 lb. per square inch. The oil used is that employed in refrigerating machinery, which thickens only slightly even at a temperature of several degrees below zero. Under average conditions the resistance afforded by each cylinder is about 4000 lb. against a piston moving at the rate of 3 ft. per second. This means a total resistance of 16,000 lb. for the four cylinders of each gate. The gate posts are designed to withstand the reaction of the cylinders together with a downward pull on the gate arm. A travel of 4 ft. by the pistons allows for a 12-ft. deflection of the 42-ft. gate.

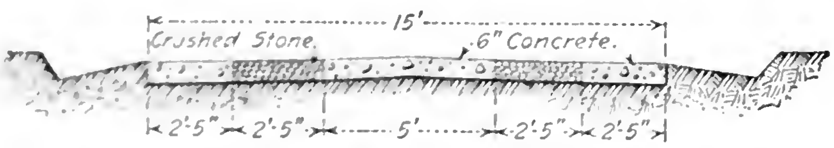
Interlocking the gate locks with the bridge-lock lever prevents operating the bridge until the gates are closed and locked, while the gates cannot be released and swung until the span is locked in its closed portion. The bridge locks are released by hand levers and the gates are swung by hand, being in charge of a bridge watchman. The 3 x 9-in. timber on the top arm of the gate is painted in diagonal stripes of black and white, and the gate is made still more conspicuous by a similarly painted plank carried above it by the gate post and a guy rod. On the top arm of each leaf is a lamp showing red toward the roadway and throwing a white light on each side to illuminate the painted arm. Warning signals are to be installed 300 ft. from the bridge.

No test, either intentional or accidental, has been made by moving vehicles. This bridge is opened only at long intervals, but is on a main highway which averages a traffic of over 3000 vehicles per day in summer, mainly automobiles. As the road is straight, most of these vehicles travel at considerable speed. The flexible yielding barrier was designed by Robert R. Evans, county engineer of Essex County, Salem, Mass.

Multiple-Strip Concrete Road to Conserve Material

BUILDING a concrete road in several strips requiring a minimum amount of material so placed that wheel-ways in both directions are provided, has been resorted to on a roadway leading to Lewis Point, St. Augustine, Fla. Duval County has since let a short stretch, and various other counties of Florida will advertise, in the near future, for a considerable mileage of this type of construction.

On the Lewis Point section, a view of which is shown, the specifications called for three strips 6 in. thick and with dimensions and arrangement as shown in the diagram. The concrete specifications call for Columbia granite in sizes from ½ to 1½ in. Lake Weir sand, which is considered one of the best sands in the state, was used. The proportions were 1 : 2 : 4. The slab was laid in one course, with ½-in. transverse-expansion joints



CROSS-SECTION OF MULTIPLE STRIP ROADWAY

every 15 ft. The concrete was thoroughly tamped and was finished by the canvas-belt method. All edges were rounded with a ½-in.-radius edging tool to obviate chipping under traffic.

The outside forms were set first in the usual way, the interior forms being left until the work was started, when they were placed in short lengths so as not to interfere with the concrete mixer. Setting the interior forms was accomplished very expeditiously by resting a templet cut to the proper crown upon the outside forms. They were set to line by means of the templet and spacers. The forms were of wood and were doweled together at the ends. When the forms are removed the space between the strips of concrete can be filled with gravel, crushed stone or other suitable material.

In normal times this road can be built in Florida for \$2.50 per square yard of concrete. A contract for 850 sq.yd. was recently let by Duval County at the rate of \$2.82. This would naturally be reduced on a larger contract. Where only single-track road is required it may be constructed of two strips from 2 to 3 ft. wide and about 8 ft. out to out.

In addition to the securing of a 15-ft. roadway with 10 ft. of concrete, another advantage is that traffic is distributed and is forced to keep to the right. It is

COMPLETED MULTIPLE-STRIP DOUBLE-TRACK ROADWAY

thought that this distribution will tend to reduce accidents and increase the life of the pavement.

The work shown was laid under the supervision of E. M. Wellman, construction engineer, of St. Augustine, and the plans and specifications were prepared by S. N. Cornwall of the National Highway Corporation, Jacksonville, Fla., who holds a patent on this type of road.

Tests of Wrapped Airplane Struts

Compression tests of wrapped and cloth-covered airplane struts made of cross-grained Sitka spruce and Douglas fir, in comparison with struts not covered, have shown that the wrapping and covering are of very little value. The Forest Products Laboratory, which carried out the tests, states that wrapping with cotton tape had no appreciable effect on strength. Governing with Bakelized canvas increased the buckling load and the deflection at time of failure; in other words, it increased both the strength and the resilience or shock-resisting capacity of the strut. However, the strength per unit of weight was decreased. The conclusion reached is that all the coverings tested have less value than the same volume of wood.

Precast Plates Form Shell of Concrete Barge

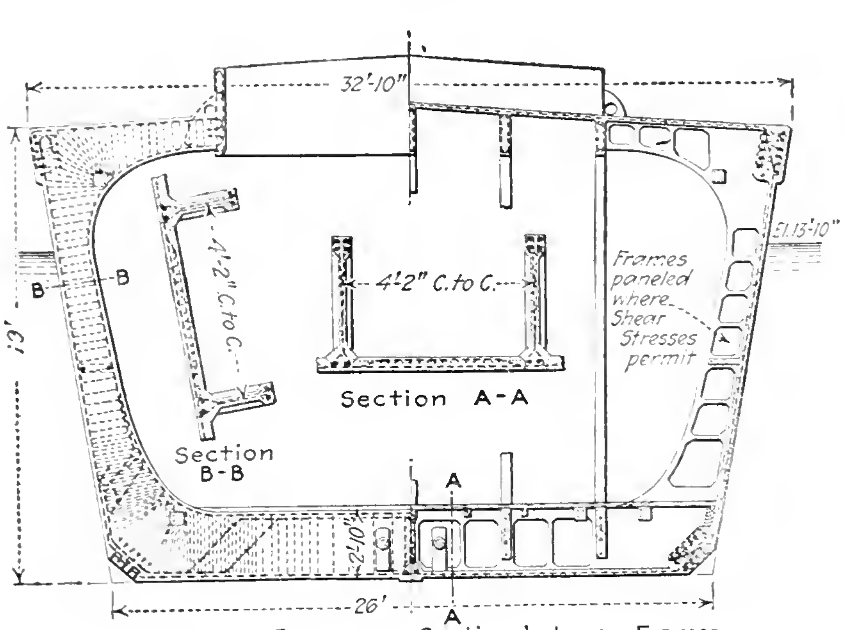
Bottom and Sides of Experimental Boat Built in British Yard Are Tied Into Frames Poured Inside of Forms

CONCRETE barges being built in a new yard in England have sides and bottoms made up of precast concrete plates fitting between the frames, which are cast in place according to the usual methods in concrete-barge construction in this country. An article by W. N. Twelvetrees in a recent issue of London *Engineering* describes the yard and the method of construction, devised by Capt. J. H. Waller, now with the British Army, but recently a civil engineer in Dublin.

The first barge built was in general accordance with the plans and specifications of the British Department of Merchant Shipbuilding. It measures 187½ ft. in length overall, 32 ft. 10 in. breadth at deck level, and 19 ft. in depth. The cross-section herewith shows the general type of design. The frames, continuous across the boat, are reinforced as shown. Longitudinal stability is insured by gunwale and bilge girders and a center keelson. All of these are poured in place at the same time as are the frames.

The bottom of the barge is formed of two rows of plates 3 in. thick, each plate being 11 ft. long by 2½ ft. wide, the end joints occurring at the bilges and center keelson, and the side joints are successive transverse frames—that is, every 4 ft. 2 in. The sides are formed of plates about 15½ ft. long by 3½ ft. wide and 3 in. thick, the end joints being at the gunwales and bilges and the side joints at successive transverse frames. The deck plates are only 2 in. thick and are jointed at the gunwales and hatch coamings. All the joints are in planes at right angles ~~to the~~ longitudinal axis of the vessel, and the edges of the plates are chamfered so as to permit the additional bond of the poured joint concrete. Rods project from the precast plates along all sides, and are bent perpendicular to the plates and twined around the bars inside the frame forms.

The plates are cast in a special yard connected by industrial track to the shipways, and are handled to the ways by derrick cars. In construction, the first work is to place the bottom plates on timbers laid across the shipways. These form the bottom of the ship, and the forms for the bottom and side frames are erected between and alongside of the bottom plates. After the side forms are up, the side plates are slipped in place, with the steel protruding and the frames poured. The deck plates are then erected, and the deck forms for the poured concrete are put in place, after which the boat is finished up.

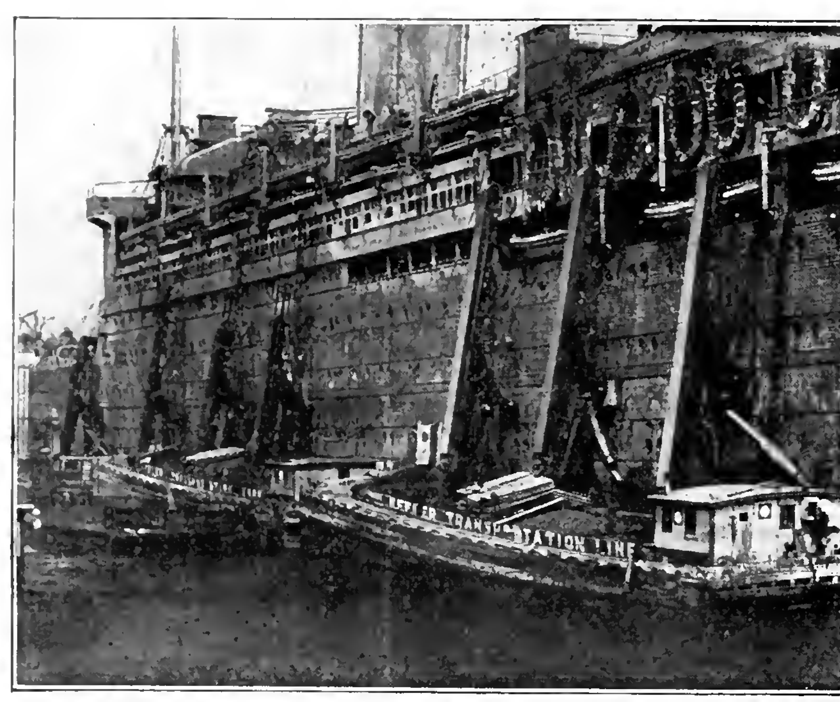


CROSS-SECTION OF BRITISH CONCRETE BARGE WITH SHELL OF PRECAST PLATES

Bucket Chain Conveyors Coal Transports

RAPID turn-around of the United States transports is being materially helped by the use of a mechanical coaling system which speeds up the filling of the coal bunkers. This apparatus has been used regularly at the Army transport bases at Hoboken, N. J., and Newport News, Va. While exact figures are not available, it is stated that the time in port has been reduced at both terminals.

The device consists of an endless-chain inclosed bucket elevator which is suspended by tackle from the side of the ship and which discharges into side ports of the vessel.



COALING THE "LEVIATHAN" WITH MECHANICAL CONVEYORS DISCHARGING INTO SIDE PORTS

When not in use the units are disposed on the adjacent pier. The elevator consists of two main members: The head, in which is installed an electric driving motor, and the leg, which slants vertically to the head and is raised and lowered as desired. The coal conveyor, of the endless-chain and bucket type, engages the coal at the boot of the leg.

When all is ready for operation the leg is raised sufficiently to allow the barge to move under it and is then lowered into the coal. The buckets lift the coal up only to the head and not to the top of the conveyor, and there permit the coal to be discharged into chutes which can be turned so that the slope will carry the coal into side ports. The view herewith shows the machine in operation on the U. S. A. transport "Leviathan" at Hoboken. The elevator is controlled by the Michener Stowage Co., New York City.

Heavy Shop Framing for 250-Ton Traveling Crane

Columns Carry Double-Deck Runways With T-Section Girders for Overhead Crane Handling Locomotives — Wood Paving

SPECIALLY heavy structural steel work is required in the repair shop now being built for the Pennsylvania Lines at Logansport, Ind., in order to carry what is believed to be the largest and most powerful electric traveling crane yet built for handling locomotives. Plate girders 5 ft. deep with 22-in. stiffening chords are supported on the H-section flanges of columns 48 in. wide. The crane has a lifting capacity of 250 tons and a span of nearly 86 ft. between the runway rails. It will pick up the heaviest locomotive and carry it over other engines to any one of the repair tracks. In addition, there are 10-ton traveling cranes of nearly 83-ft. span, which operate on runway girders below those of the larger crane.

The repair shop is 420 x 195 ft. and has its width divided into three bays: A 90-ft. erecting shop with 54 ft. clear height, a 73-ft. heavy machine shop 34 ft. high, and a 30-ft. light machine shop with a mezzanine floor for tool room, toilet rooms and the smaller classes of machines. The columns are spaced 24 ft. on centers, except that in the two end panels the spacing is 30 ft. Trusses carry the roofs of the two larger bays. In the 75-ft. bay each third panel of the roof has the purlins carried by the bottom instead of the top chords of the trusses, thus forming a series of transverse monitors which provide for light and ventilation. In the 30-ft. bay the roof is carried by I-beams. The upper floor in this bay has steel framing incased in concrete and covered with a concrete slab on which is laid wood-block paving. This floor is designed for 300-lb. live load and 100-lb. dead load.

A T-section is used for the columns of the erecting shop. It consists of a 48-in. web plate with flange angles, and a heavy inner flange composed of one 18-in. I-beam and two 15-in. channels, as represented in Fig. 3. This flange carries the runway for the 250-ton crane, while the rest of the column section, narrowing to 24-in. width, extends up to carry the roof trusses. Separate columns are provided for the runway girders of the 10-ton cranes; these are 12-in. I-beams, placed just inside the main columns and tied to the latter by diaphragms. These posts rest on the same bedplates and footings as the main columns, but have separate shoes and anchor bolts.

The runway girders for the 250-ton crane are 60½ in. deep, and are of the section sketched in Fig. 3. (See next page). The top flange is a horizontal girder composed of a 22-in. plate with four flange angles, the 150-lb. crane rail being laid on this web plate and secured by horizontal bolts which pass through the web of the rail and the upper flange angles on the plate. The flange is capable of taking a side thrust equal to 10% of the lifting capacity of the crane. In the design of the girders 25% was added to the live road to allow for impact. The wide top chord provides resistance for

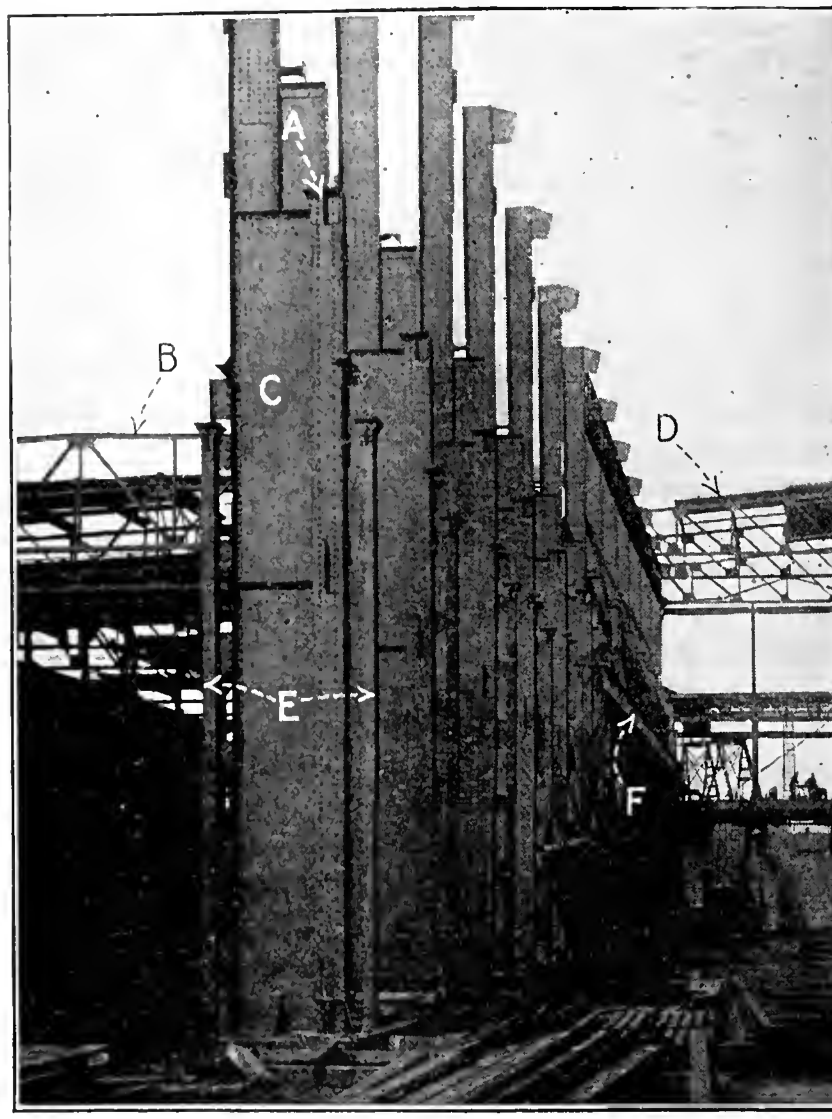


FIG. 1. HEAVY COLUMNS FOR 250-TON 86-FOOT CRANE IN RAILROAD REPAIR SHOP

a side thrust equal to 10% of the lifting capacity.

In the case of the 28-in. I-beam runways for the 10-ton cranes, lateral stiffening was provided by riveting a horizontal 10-in. channel to the upper part of the web; this channel bears against the face of the column. The

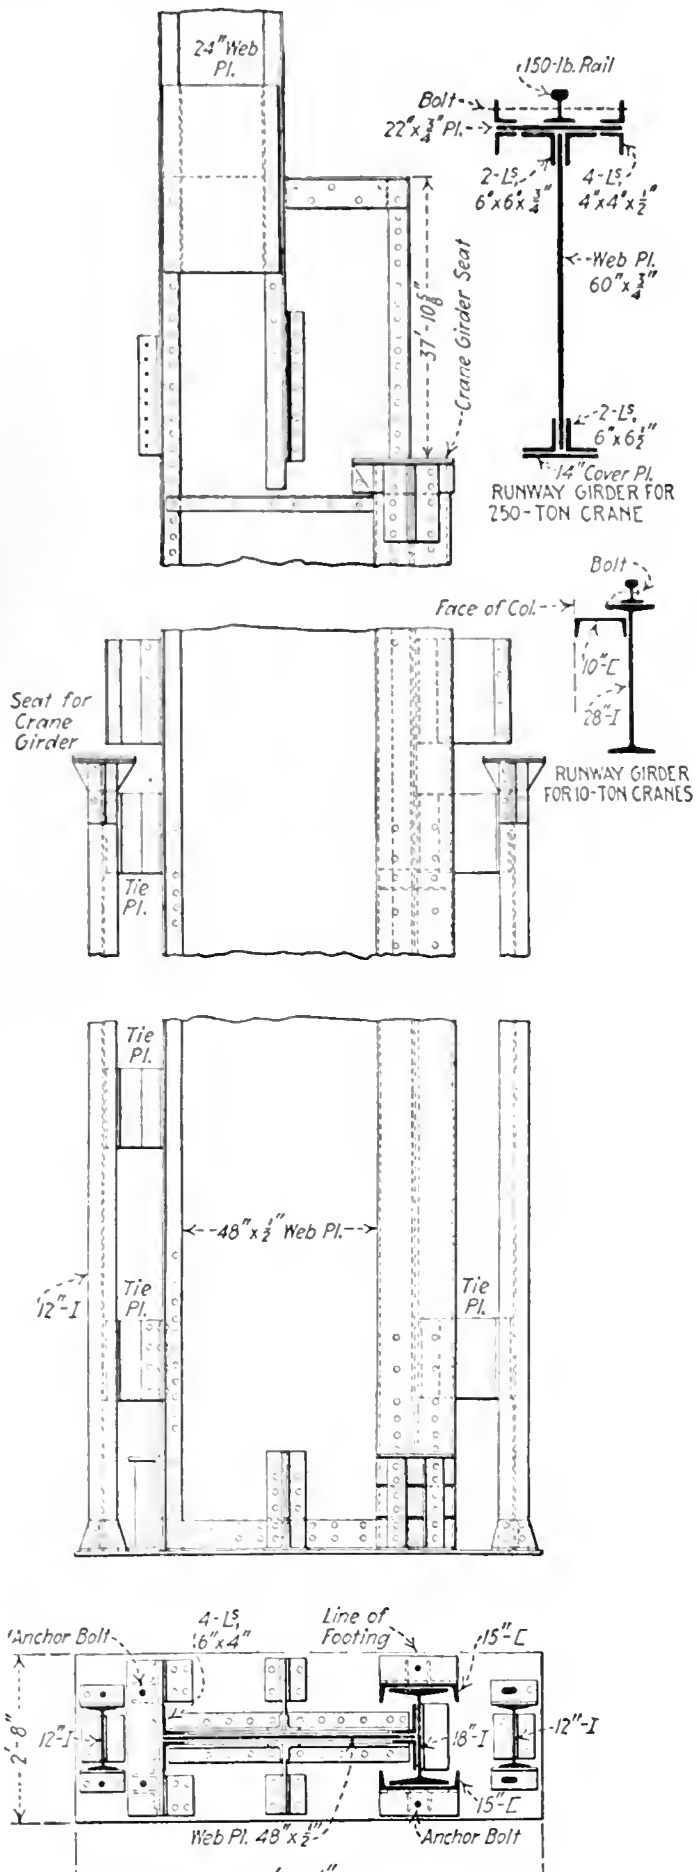

FIG. 3. CRANE COLUMNS AND GIRDERS

60-lb. crane rail is secured at 48-in. intervals by bent hook-bolts, alternating on opposite sides of the rail, engaging the edge of the I-beam flange.

Concrete sills are used in the brick walls, being found considerably cheaper than the stone ordinarily used. Wood-block paving $3\frac{1}{2}$ in. thick, laid with tar cushion on a concrete base, covers the entire area of the first floor, except that the concrete walls of the pits in the erecting shop are capped with 5 x 9-in. oak timbers to form supports for the jacks used in raising or blocking up the engines.

For lifting locomotives the large crane has two hoisting trolleys, each of 125 tons capacity, which are normally spaced about 45 ft. on centers and pick up the engine by both ends. Each trolley has also a 10-ton auxiliary hoist. Magnetic control is employed throughout, with dynamic control on each hoist. The crane has each end of its bridge carried by a group of eight wheels mounted in double compensating trucks and equipped with an electric motor, so that each group of wheels is driven independently.

Across the floor of the erecting shop are 17 parallel transverse stub tracks, three of which extend into the machine shop and each of which has a 56-ft. repair pit. These tracks are spaced 24 ft. on centers and are at right angles to the crane runways. They extend 20 ft. outside the building to the pit of a 60-ft. transfer table of 250-ton carrying capacity, and having a 75-hp. electric motor which operates it at a high speed of 100 ft. per minute when carrying an engine. This table has a travel of 540 ft., running beyond the ends of the building so as to connect with yard tracks on which engines are moved to and from the transfer table.

This new shop was built by the Austin Co., Cleveland, Ohio, which also made the plans for it, subject to the requirements of the engineering and mechanical departments of the railway. J. E. Anderson was the company's superintendent of construction. All work is under the direction of Robert Trimble, chief engineer of construction, Pennsylvania Lines. W. E. Guignon is division engineer at Logansport, with T. L. Doyle as assistant division engineer.

Some Engineering Problems of Regional Planning

By Morris Knowles

Chief Engineer, Housing Department, Emergency Fleet Corporation, United States Shipping Board

Abstract of paper read before the National Conference on City Planning, held two weeks ago at Niagara Falls and Buffalo—Solution requires comprehensive planning of all features with consideration of their relation to one another, for greatest good at lowest cost.

TOWN planning as a conscious art had its birth in the desire to add beauty and attractiveness to towns for which, it was at first assumed, the problems of convenience, sanitation and amenity had already been reasonably well solved. Therefore many town planners, enthusiastic in their quest for "the city beautiful," lost sight at times of the engineering problems of town planning. But all this is changed now, for experience has proved the interdependence, in city building, of beauty, convenience, sanitation, amenity and economy. And so, from being a question of art, town planning has become more and more one of engineering.

Regional planning is still newer as a conscious art. Born from the efforts of neighboring towns to coöperate in the solution of their joint engineering and utility problems, it has developed until today its ideals, as applied to regions, are as broad as are those of town planning.

The origin of this new art guarantees from the start that its dependence upon engineering will be recognized. Beauty is as vitally necessary in regions as in towns;

but, as the region is a little more remote from the individual than is the town, it is easier to see that the prerequisites of beauty are sanitation, convenience, amenity and economy, and that many of the most important problems of regional planning are engineering problems.

Among the problems to be studied are those associated with the geographical and industrial characteristics of the region; the development and interconnection of steam, electric and water transportation; the arrangement and construction of main highways; joint water and sewerage systems; the regulation of streams; the supply and distribution of light and power; the organization of regional utilities, and the apportionment of the cost of regional works.

Survey—The first requisite of a regional plan is a comprehensive survey of the topography, geography, population, natural resources, agriculture, industry and trade of the region, much of which is an engineering study. And one result of such study should be a complete topographic map of the area, which may serve as a base map for the regional plan. Not only should this map show the topography, and locations of the towns, railroads, streams, canals and other natural and structural features, but the data on natural resources, agriculture and industry should be correlated with the map in such manner that maps may be prepared showing the relative distribution of all the factors affecting the life of the region.

Steam and Electric Transportation—Steam railroads are the arteries through which the life-blood of our country's trade flows. Regional planning must take into account the fact that steam railroads are best adapted for long-haul, through traffic. It must, of course, be based upon the existing railroad systems, and must provide yards and terminal facilities, both for facilitating through movement and for transfer to local, short-haul roads and to electric and water transportation routes. The study of electrification must be continued in connection with the elimination of noise and dirt from our cities, and with the general power program for the region in which the railroad is located. And a new type of organization and regulation must be found which will at the same time protect the public interest and encourage growth sufficiently to serve the needs of industry. The electric roads are the natural complements of the steam railroads.

Regional planning will recognize more clearly than ever before the necessity for interconnecting the various types of transportation routes, for building joint terminals, with adequate wharves, docks, warehouses, railroad yards, cranes and electric facilities, so that the transfer and transshipment of passengers and freight may be accomplished most economically and most efficiently, and so as to secure the greatest usefulness from the transportation system as a whole.

Main Highways—If the railroads are the arteries of trade, then the highways are the vessels through which the individuals engaged in commerce receive the blood which quickens their lives. But regional planning cannot permit the location and construction of the highways of the future as have been many of those of the past. Main roads will no longer be located with reference to section or property lines, but with reference to topography, the distribution of products creating traffic streams, and the coordination of the highway system with the railroads, electric lines and waterways; and types of construction will be carefully adapted to traffic needs—not only as to road widths, but also as to gradients, surfacing and drainage.

The regional plan, therefore, should provide a program harmonious with the programs for the solutions of the other problems of the region, which may serve as a guide for the construction of main highways during years to come.

Water and Sewerage Systems—The advantages of regional water and sewerage systems are often particularly striking, and serve excellently to illustrate the value of the regional plan. Water-supply problems depend for their solution more upon the source of supply than upon any other consideration. Sewerage is strictly a drainage-area problem, and unnecessary expense as well as mutual damages of many kinds result from attempts to solve it with respect to political boundaries alone.

Stream Regulation—Another problem for which satisfactory local solutions are obviously impossible and drainage-area solutions absolutely indispensable is that of stream regulation and water conservation. Navigation requires a uniform, sufficient depth of water throughout the navigable length of the stream. Local flood-protection works may actually increase flood heights above or below them. The interdependence of the water and sewerage problems of communities within a region has already been pointed out. The best utilization of water-power requires that its development and distribution be based on regional, and not on local, considerations. It is of great importance that stream regulation be based upon the consideration of all the uses of water, and not on one of the above.

Light and Power—The type and the locations of regional sources of light and power will depend largely upon the characteristics of the region with respect to availability and location of coal, natural gas and hydroelectric power. But the economic advantages of power generation in large central station need no demonstration in these days of efficient, large-capacity generators and of high-tension transmission. Enlightened self-interest has long recognized this, and the results may be seen in the unification of the gas-supply systems in the neighborhood of every field of natural gas, and in the huge electric central stations and the network of electric-supply and distribution lines which characterize every one of our large urban districts.

Organization—Organization for carrying out the works of a regional plan is not solely an engineering problem. Existing political organizations must, of course, be the basis of it, and intricate legal and organization problems must be solved to build up the group of related organizations (for each problem may require separate organization), required to secure the results desired. But the selection of desirable types of organization is so closely tied up with the planning and use of the public works involved in a regional plan that no consideration of its engineering problems would be complete without reference to it.

The type of organization depends in each case not only upon the existing political organization and upon the area and density of population of the region, but also upon the particular purpose or combination of purposes to be accomplished. Dependent upon these factors, examples of community coöperation can be found,

varying through a wide range with respect to the functions involved, the degree of centralization of control, and the methods used in financing and apportioning cost.

Most of the important cases, however, can be classified under one or another of six heads, as follows: (1) Extension of municipal limits, and consolidation or annexation; (2) extension of municipal jurisdiction; (3) contracts between municipalities; (4) county administration; (5) private enterprise and (6) district organization.

Within a given region, each of these types of organization may be represented. But the conception of regional planning contemplates the direction and guidance of all of them by the regional plan—that the plan shall be a kind of regional constitution with which the subsidiary organizations of the same region must not conflict.

Apportionment of Cost—Like the problem of organization, apportionment of cost is in large degree a financial, legal and political problem, but, like the selection of organization types also, it is so closely bound up with the use of public works that it is largely an engineering problem, too. In most cases, the method used may be classified under one of four headings, or as a combination of more than one of them, as follows: (1) General taxation; (2) regional general taxation; (3) special assessment, and (4) rates based upon quantity of service used.

Conclusion—The great engineering problem of regional planning is the comprehensive planning of all of the features with consideration of their relation to one another, so as to secure the greatest good at the lowest possible cost. Steam transportation must not be developed without references to or in unnecessary competition with electric and water transportation. Main highways must not be planned solely with a view to carrying through traffic—if, for example, a slight modification of the location of a boulevard would provide a right-of-way for a trunk sewer and avoid the condemnation of expensive additional property, it would be indefensible to fail to consider it. Sewage outlets must not be located without reference to water intakes. Stream regulation must not be studied for one purpose, but consideration must be given to water transportation, flood prevention, water-supply, sewage dilution and power development, so as to secure that combination of results which represents the greatest good per dollar spent for the entire region.

If this broad engineering conception of regional planning can be kept before us, all of the inherent advantages can be realized and its future will hold for mankind a store of benefits as much greater than those which have come from town planning as its field is more extended.

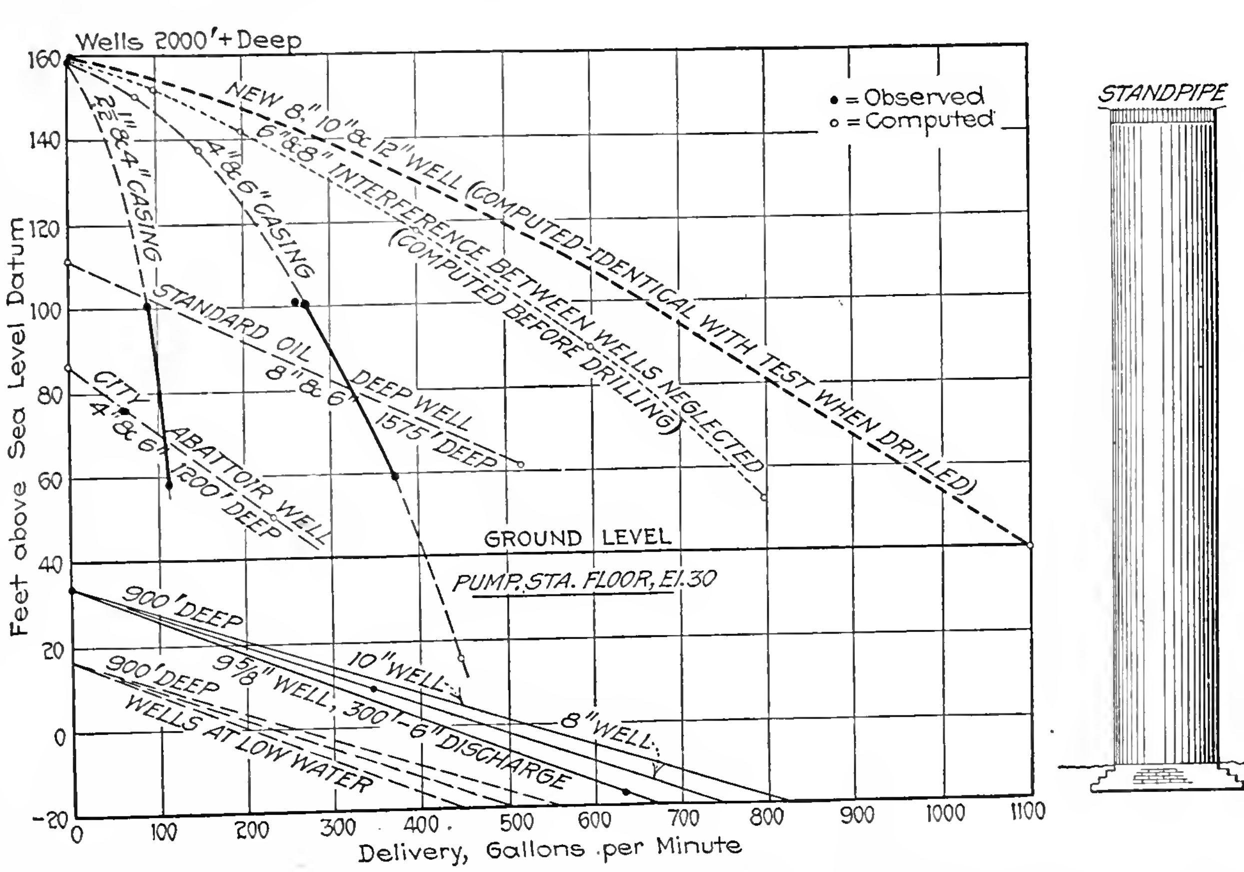
Artesian Well Experience at Baton Rouge, Louisiana

Larger Well Casing Gives Increased Flow — Temperature a Factor in Yield — Well Sunk About 2000 Feet in 62 Days

FOURTEEN artesian water-bearing strata 5 to 194 ft. in thickness, all of which are separated by thick layers of tough blue clay, underlie the City of Baton Rouge, La. A report by Alvord & Burdick, following exhaustive exploration tests to various depths for the Baton Rouge Water Co., indicated that at the 2000-ft. level a suitable soft water under high head would be obtained. L. R. Howson, of the firm, described certain features of the unusual ground water-supply conditions, at a recent meeting of the Illinois Section of the American Water-Works Association. Salient points in his paper are given in the following abstract:

As no rock is encountered and the holes must be cased the entire depth through the many strata, some of which cave badly into the larger holes, it was thought that the largest casing that could be successfully lowered into place, on account of the great length to be supported, would be 8 in. for the top 1300 ft. and 6 in. for the remainder of the depth. It was estimated that such a well would yield 840 gal. per minute free flow at the ground surface, since the static head is 120 ft. above the ground level. When the well was sunk, however, the contractor, W. M. Eberhart, was persuaded by the water company, despite the fact that he was not to be paid according to yield, to attempt a larger casing than had been used heretofore in the vicinity. Accordingly, he placed 915 ft. of 12-in., 934 ft. of 10-in., 44 ft. of 8-in. casing, and a 70-ft. strainer consisting of perforated well casing wound with brass gauze.

A flow of 1100 gal. per minute at the ground surface was secured, the increase over that expected with the 8- and 6-in. sizes originally proposed being due to the smaller friction losses in the larger casing. When the



RELATION BETWEEN YIELD OF WELLS AND LOWERING OF STATIC WATER LEVELS

large well is delivering at the 1100 gal. per minute rate approximately 50% of the total head loss is due to actual lowering of the water level, and the remainder to frictional resistance in the well casing. With the 6- and 4-in. well flowing at the ground surface the total head lost is consumed in the ratio of 25% for the draw-down and 75% for friction, the large pipes giving more than double the amount of water under similar conditions. At 2050 ft. a 60-ft. sand layer was penetrated, which produced a well having specific capacities, or yield for each foot the static level is lowered, of from 12 to 15 gal. per minute and a temperature of 92° F. The static water level is 160 ft. above sea level, or 120 ft. above the ground surface.

Tests on existing wells of the company gave the following data: From wells 200 to 400 ft. deep the static elevation of the water is near sea level, and the temperature is 64° F. Baton Rouge is 40 ft. above sea level. Wells 800 to 900 ft. deep penetrate a 50-ft. sand layer, yielding 10 to 12 gal. per minute per foot of draw-down from 6- to 12-in. walls. The temperature is 72°, and the static level is 35 ft. above sea level. From a sand layer at the 1320 to 1350-ft. depth a water of 85° temperature rises 110 ft. above sea level, but the specific capacity is only from 1 to 2 from a well of the water company and 6½ from a city well recently drilled.

The various gravel and clay strata under Baton Rouge dip to the south 20 ft. to the mile, so that a porous stratum outcropping near Jackson, Miss., is penetrated at Baton Rouge, 125 miles to the south, at 2050 ft. below sea level. Over an area of 20,000 square miles just south of the Louisiana-Mississippi line the surface becomes rolling and rises rapidly to from 200 to 400 ft. above sea level. Above 100 ft. it is gravelly and presents an excellent collector.

The gravel strata are separated by light, impervious material which prevents interconnection and accounts for the variation in static pressures. The variation in temperature is important because well yields depend upon the rate of flow through the sand, and water at the 92° of the 2000-ft. depth passes through sand, of the character and size encountered, 175% faster than would water at 50 degrees.

The diagram indicates the relation between the yield of the wells tapping the various strata and the lowering of the static water levels. It also shows the effect of friction in cutting down yield very materially when the water must rise through two-fifths of a mile of 4- and 6-in. casing, as compared with the larger sizes.

The well was drilled by the rotary process and tested, all in 62 days, or at an average rate of nearly 34 ft. per day. The contractor first ran a 10-in. fishtail drill until he located a suitable foundation in tough blue clay for the 12-in. casing at a depth of 915 ft.; then reamed the hole to a 16-in. size, "slushed" the hole to insure its standing open, and inserted the 12-in. casing. This "slushing" is accomplished by pumping a mixture of clay and water to the bottom of the hole. As it passes upward outside of the pipe the clay particles seal up the sides of the well and hole, and by their cohesive properties preserve the hole until the casing can be inserted and lowered to position.

The assembling and lowering of 915 ft. of 12-in. pipe required 7½ hours. Four days' time was allowed for the sand to set around this casing before drilling for the 10-in. casing was started. Similar methods were followed for the 10-in. and 8-in. casing and the 70-ft. strainer.

A large number of wells have been drilled in and near Baton Rouge in addition to that of the water company, the most important being the group of 14 wells drilled by the Standard Oil Co. to supply cooling and condensing water for its oil refinery. These wells furnish nearly 5,000,000 gal. per day. This water is, of course, air-cooled, but all the city water must be iced before using.

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

More English, Not Greek and Latin

Sir—Anent the discussion of Latin and Greek for engineers, I wonder that it has never occurred to the people who criticise the engineer for his narrowness of training and outlook that there are others. An experience of a good many years of association with educated people in other lines leads me to the conclusion that the engineer is not peculiar in having a somewhat narrow outlook and that, indeed, he is less of an offender, if this be an offence, then a good many other persons presumed to be of at least equal training. True it is that the engineer is more familiar with the doing of things than with the telling about things. True it is that he has what perhaps may be called a geometric imagination, an imagination that sees great constructions rather than one that hears beautiful music, conceives of beautiful thoughts, or sees the results of the application of political or business principles; and I am disposed to agree that his training in verbal expression in the schools is not what it should be.

With what seems to me to be a characteristic engineering habit, I would go directly rather than in a roundabout way to the cure of the difficulty. It is more and better English that we want. The study of Latin and Greek will undoubtedly help in securing facility in the use of English, but would it do this to the same degree that an equivalent time spent on the study of English would do?

By all means let us do everything possible in school to give breadth of vision and facility of expression to all students of all professions, but let us not try to make teachers, orators, poets, or story tellers out of those people who, because of their peculiar type of mind, are intended to do the constructional work of the world.

And let us not make too much of the narrowness of vision of the engineer. A considerable experience as an engineer-witness leads me to the conclusion that the average lawyer is not a more logical thinker than the engineer; and long experience in mixing with teachers of language, economics, philosophy, mathematics and all other subjects that are sometimes called cultural leads me to the conclusion that the average teacher of these subjects has a not appreciably greater breadth of vision than the average engineering teacher; and a fortunately limited experience with healers of our bodies and a more or less extended acquaintance with the curers of our souls leads me to the conclusion that neither physi-

cians nor ministers as a class have a much greater breadth of vision than the engineer.

I think we are inclined to magnify our faults because we are of an analytical type of mind, and it is well that we should see our faults, but let us in characteristic engineering fashion proceed to cure these in the most direct manner.

WILLIAM G. RAYMOND,
Dean, College of Applied Science, State University of Iowa.
Iowa City, Iowa.

Flue Lining Would Protect Faulty Chimney

Sir—The fire in the officers' quarters at the United States Army General Hospital No. 3, Colonia, N. J., which is reported in *Engineering News-Record* of May 8, 1919, p. 929, is very much like the reports of a large percentage of the residence fires that are reported from day to day in the daily newspapers: "It started from the chimney." The National Board of Underwriters' reports show from year to year that a larger number of fires, entailing an enormous loss, are caused by defective chimney construction than from any other one known cause.

The materials which this expert brick mason used, in the construction of this particular chimney, would have made a thoroughly safe and satisfactory chimney had the mason looked around a little more and found a few pieces of fireclay flue lining to line the chimney. In all probability, the material was there, because the Government specified such lining in all flue construction at the cantonments. It makes a chimney fireproof and foolproof. The unvoiced criticism of the engineers that the medical officers should not undertake to build a chimney is thoroughly justified, for any of the engineers in the service would undoubtedly have lined the chimneys.

G. H. TEFFT,
Secretary and General Manager,
Chicago, Ill. Clay Products Association.

Special Stadia Methods Used in Florida

Sir—On reading the description of the methods used in the stadia survey at Columbus, Ohio, in *Engineering News-Record* of Apr. 17, 1919, p. 776, it occurred to the writer that the methods used by Cunningham and Hallowes, chief engineers of the North St. Lucie River Drainage District, might be of interest to the profession. This district covers 75,000 acres, being approximately 9 x 14 miles in area. As a topographical map was desired on which to base a plan of reclamation, the first move was to run transit and level lines along the section lines the long way of the district, to be used as base lines for the topographical work. Topography parties were made up of five men each: Instrument man, recorder, and three boardmen, it being found that with a party so balanced all hands were kept busy. By working back and forth between base lines, it was not necessary to try for as great a degree of accuracy as would otherwise have been necessary on long traverses.

With this fact in view, instead of setting over the last hub established and continuing the line ahead, the transitman skipped the hub and proceeded to such point as he might select for the next set-up. As azimuths were worked on the full circle, he then set the vernier at zero, dropped the needle, clamped the instrument in meridian, took a back sight reading the azimuth on the "B" vernier, which caused his notes to read as if he had actually set up on the hub and projected the line ahead. This saved the time of one set-up; or, in other words, he made just half as many set-ups as under the old methods, which amounted to a considerable saving in time and expense on a job of this size.

The stadia boards were 14 ft. long and 3 in. wide and were made of cedar at a local boat yard. They consisted of two 7-ft. sections connected with two light strap hinges—two hinges were necessary to overcome a tendency toward side sway. A fish or splice 2 ft. in length was fastened with screws on the back of the top of the bottom section of the rod, in such shape that it extended 1 ft. above and formed a ridged connection when the rod was opened out and fastened with a wing nut.

The first rods tried were graduated in figures the same as ordinary level rods, but on account of low visibility this was abandoned in favor of a character design of yellow, white and black. For the fifth and eleventh foot marks, the white was omitted, the graduations being made in yellow and black for quick identification.

The back of the rod was divided into feet of alternate yellow and black, the fifth and eleventh foot marks being black with a yellow diamond inclosed. It was only used when the sight was obscured or blurred for some reason. Sights of 2000 ft. were frequently made with this rod. This same equipment and methods were used in investigating the drainage outside the district, with very satisfactory results. Considerably more care was taken with the instrumental work, however, and sights were usually confined to about 1400 or 1500 ft. While some of these outside traverses were several miles in length there was no trouble in obtaining proper closures.

The notes were plotted with a universal drafting machine, only the turning points and instrument points being plotted first, to check the closure. As the azimuths were all based on magnetic north, the draftsman set off the variation on his machine and then plotted direct from the notes. After a little practice he was able to transfer the notes to his map about as fast as an assistant could read them.

Fort Pierce, Fla. A. D. CUNNINGHAM.

Chart for Solution of Manning Formula

Sir—Unfortunately, I find that the instructions for the use of my chart for the solution of the Manning formula, reproduced on p. 1126 of your issue of June 5, 1919, were not reproduced. The method of using the chart is as follows:

Starting from the proper value of the hydraulic radius, move vertically to the intersection with the roughness-factor line, then horizontally to the slope line, and vertically to the resultant value of the velocity on the upper scale.

If the desired velocity is known, but not the slope, find the intersections of a vertical line through the proper velocity with a horizonal line through the intersection of the hydraulic radius and roughness-factor lines, and read off the desired slope on the chart.

The following correction should be made: Slope line s, numbered 0.00003 on the chart, should be numbered 0.00002.

MORTIMER F. SAYRE,
Assistant Professor of Applied Mechanics, Union College.
Schenectady, N. Y.

HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Flood-Basin Wood Lots Logged For Construction Timber

MODERN forestry, as well as the engineering construction of dams and river channels, is one of the operations which are to make the Miami River Valley of Ohio safe from floods. When 2 x 2 x 24-ft. spuds were wanted for the scows to carry the 200-ton dragline excavators which are widening and deepening the river channel at Dayton, the trees were cut from the wood lots of the conservancy district. This is merely an example. Altogether, some 350,000 ft. b.m. of lumber used in construction, besides over 50,000 lin.ft. of piling and cribbing, have been provided from the same source. In addition, a great amount of timber on the stump has been sold to manufacturers who use mature, high-grade hardwoods in the making of their products. Only matured timber has been cut.

Other Articles in This Issue of Interest to Contractors:

There are about 120 wood lots, varying in area from one acre to 100 acres, in the five large flood-detention basins of the Miami Conservancy District. These wood lots are quite generally distributed, but the greatest amount of timber is in the Huffman and Englewood basins. The Germantown and Taylorsville basins rank next, and the Lockington basin is fifth. All the basins contain about 6,000,000 ft. b.m. of merchantable timber. Nearly all of the timber is hardwood. About 37% is oak and 14% is maple, and there are from 5 to 9% each of ash, birch, elm and hickory. Many of the trees are finely matured specimens of their kinds.

Upon assuming control of the wood lots, the directors of the flood-protection works had careful surveys made and, on the information obtained, a plan of conservation, planting and cutting was mapped out. The theory adopted was that timber was a crop to be harvested when ripe and disposed of for gain. Being a crop, only mature timber, that which would never be worth more than at present, was to be cut. Trees which had not reached maturity were to be left to grow, and growth and quality were to be encouraged by proper thinning out and by the removal of underbrush. In brief, modern, scientific forestry practice was to be applied to the district's woodland properties. This development is making progress, and is to be followed in time by proper planting and reforestation operations suited to the circumstances.

Utilization of the matured timber is the operation of chief interest to the engineer and contractor. Only matured trees, as stated, will be cut. An exception is made to this rule in the cases of wood lots that are on low ground and located not far up-stream from the dams. As a flood which would partly fill the basins would cover these woods and, if the water remained a few days, would probably kill the trees, these low-lying

LOGGING WHITE OAK FOR 24 x 24 INCH x 24-FOOT SPUDS FOR DREDGE SCOW ON DAYTON CHANNEL EXCAVATION

woods will be cleared completely. But the utilization will, nevertheless, be thorough. Each size and kind of timber will be turned into the sort and dimensions of lumber for which it is best suited, and the waste of proper size will be prepared and disposed of for fuel. Only the absolutely unmarketable trash will be destroyed by burning.

Specific examples illustrate best the manner of handling the timber crop in the wood lots which will be preserved. Surveys of the wood lots disclosed some 400 or more matured walnut trees; these were sold to a firm manufacturing gun-stocks and to another which makes churns. In the same manner, some 130,000 ft. b.m. of white and blue ash were sold to a firm manufacturing shovel and hoe handles. In all cases, the trees were cut and shipped in the log to be sawed at the factories. For use in constructing the flood-protection works the trees are cut by the district and hauled to conveniently situated commercial sawmills, to be sawed according to orders. For example, the large timbers for scow spuds were hauled to Dayton, where the timber was to be used and where it happened, also, there was the only nearby mill equipped to saw pieces of such large size. The trees were cut by the conservancy logging crew, were loaded onto wagons in the woods and were hauled by a 10-horse team, one log to a load, to a yard on the main road. At the yard the logs were loaded one at a time onto a motor truck and trailer and hauled to the mill. Timber cut from the conservancy woodlands for the conservancy work is charged against the item for which it is used, on the basis of a stumpage price plus the labor cost of producing the lumber. This is, of course, a purely bookkeeping charge.

The forestry work of the conservancy district is directed by J. W. Calland, on leave of absence from the Ohio Forestry Department. S. Graham Smith is director of the district farm lands on which the wood lots are located.

Job Labor Records Kept on Two Forms

TWO card forms kept by the foremen and the job clerk are used for recording time, labor and cost distribution, and payroll disbursements, on concrete-bridge construction at Columbus, Ohio. The bridge is a seven-span arch structure involving the placing of about 18,000 cu.yd. of concrete, with excavation and cofferdam, and also the wrecking of an old bridge structure.

The foreman's card is filled out and turned in daily.

WORKMAN'S TIME AND PAYROLL BLANK, USED ON BRIDGE CONSTRUCTION WORK

Besides the spaces shown for equipment and excavation there are similar spaces for "Concrete, Class A," "Concrete, Class B," "Cofferdam," "Wrecking Old Bridge," "Screening Gravel," and three blank spaces. The workman's card is kept by the job clerk, who enters the figures from the foreman's daily report, as indicated by the sample. From these two original records, cost sheets can be made up and all needed bookkeeping entries made.

The contractors for this work are the Olson-Magee Co. & O. H. Olson, of Kansas City, Mo.

Tractor Pumps Oil from Cars to Tank

By Albert S. Fry
Morgan Engineering Co., Memphis, Tenn.

FIELD tanks which store the fuel oil for the walking dragline excavators which are building levee for the Inter River Drainage District in Missouri are filled by pumping from tank cars by a centrifugal pump operated by a tractor.

To have installed an engine to run a pump to unload tank cars would have been costly. Instead, a small centrifugal pump was set up and, whenever a car is to be unloaded, a tractor is disengaged from some other part of the work and is used to furnish power for the pump. One tractor is used to serve two of the tanks on this work, so this method of operation has been particularly efficient.

The unloading of the oil takes only a small part of the tractor's total time, the greater part being spent in general hauling and right-of-way clearing. On the latter work the tractor has proved its worth in dragging logs out of the cleared area.

News of the Week

New York, June 12, 1919

Townsend Highway Bill Reintroduced in Congress

The Townsend highway bill, introduced in the last session of Congress and described in *Engineering News-Record* of Feb. 27, p. 446, has been introduced in the present Congress in slightly modified form. The bill has been considerably shortened, and provisions which were in the Federal-aid highway provisions of the Postoffice appropriation bill in the last session have been omitted.

Among the principal changes is the reduction of the number of commissioners from five to three, decreasing their terms from seven to six years. The bill provides that not more than two of the commissioners may be of the same political party. In cases where states have so framed their highway laws that they can take advantage of Federal aid only through the Secretary of Agriculture, he shall act jointly with the proposed Federal Highway Commission in administering the Federal-aid law in those states.

All present Governmental road agencies, with the exception of those pertaining to the War and Navy Departments, are transferred to the proposed new commission.

The officers and salaries provided for in the previous bill are left practically unchanged, as are the appropriations, with the exception that those appropriations for Federal aid provided in the last bill are omitted. All appointees such as clerical or other official assistants, with the exception of the chief engineer, secretary and attorney, shall be taken from the classified civil service; provided, however, that Army engineers may be employed by the commission without civil service procedure. The plan of distribution among the various states, prescribed in the previous bill, is also omitted.

United States Sells Ships at High Prices

Several steel steamers have recently been sold by the U. S. Shipping Board at prices of $210 per dead-weight ton, according to an announcement made by Chairman E. N. Hurley last Friday. A 7500-ton freighter went to the National Shipping Corporation at New York at this figure, and a 5075-ton vessel to the Omega Steamship Co. of the same place; offers for four other ships at the same price have also been received. The Skinner & Eddy Shipbuilding Corporation has offered to buy at present construction costs four 8000-ton freighters being built at the yards of that corporation.

Employment Bureaus

Engineering Societies' Employment Bureau of the four founder societies, conducted by Engineering Council Employment service, for members and for other professional men introduced by members. Especial attention for those released from Government service. Address, 29 W. 39th St., New York City.

American Association of Engineers, 29 S. La Salle St., Chicago. Service to members only, but Army or Navy Engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

Engineers' Service Bureau, 57 Post St., San Francisco. Only applications by mail or wire will be considered.

Professional and Special Section, United States Employment Service, 469 Fifth Ave., New York City.

Reëmployment Committee of New York City for Soldiers, Sailors and Marines, 233 Broadway, New York City.

Pittsburgh Asks Architects' Aid in Designing Bridges

Three achitects have been engaged by the county commissioners of Allegheny County (Pittsburgh) to act as advisers to County Engineer J. G. Chalfant in the design of three new river bridges which the county is preparing to build. Benno Janssen, of Pittsburgh, will deal with the design of the 40th St. bridge over the Allegheny River (replacing the existing 43rd St. bridge). Alden & Harlow, of Pittsburgh, will serve in connection with the Monongahela River bridge connecting Wilson and Glassport, while Warren & Wetmore, of New York, are retained for the new 16th St. bridge over the Allegheny River. This action follows the recommendation of the Art Commission, concurred in by the planning commission recently appointed by the county commissioners.

Study Missouri River Water-Power in South Dakota

A hydro-electric commission has been appointed in South Dakota, under an act of the legislature, for the purpose of investigating the water-power resources of the Missouri River in that state. This commission has engaged Daniel W. Mead and Charles V. Seastone, consulting engineers, Madison, Wis., to investigate and report.

Trouble With Bascule Bridge in Buffalo

Partial dropping of a bascule bridge in Buffalo recently, which blocked the span for a time, was caused by the operating gearing getting out of mesh. George H. Norton, city engineer, describes the circumstances as follows:

The South Michigan Ave. bridge over the city ship canal is a rolling-lift span of 110 ft., erected in 1904. The rolling girders or segments have shoe plates of 2-in. rolled steel which were bent and turned in a lathe to 20-ft. radius and have mortise holes which engage with lugs on the cast-steel track plates on the foundation girders. These rolled shoe plates had cracked and broken out around the lugs so as to allow the structure to shift in position.

Endeavor was made to have new plates constructed for this purpose, but, as this type of bridge is now using cast-steel segmental shoes for this purpose, after consideration it was decided to repair the plates by the electric welding process. This work is now under way. The shifting of the span on its track plates somewhat racked the operating machinery so as to allow the operating gear to slip, allowing the span to drop a short distance, but without injury to the span itself. The shifting in position made it impossible to land the span for a time and also impossible to operate it until the machinery gearing had again been placed in mesh. The most serious difficulty has been from delay to navigation for several short periods in the adjustment of the operating machinery.

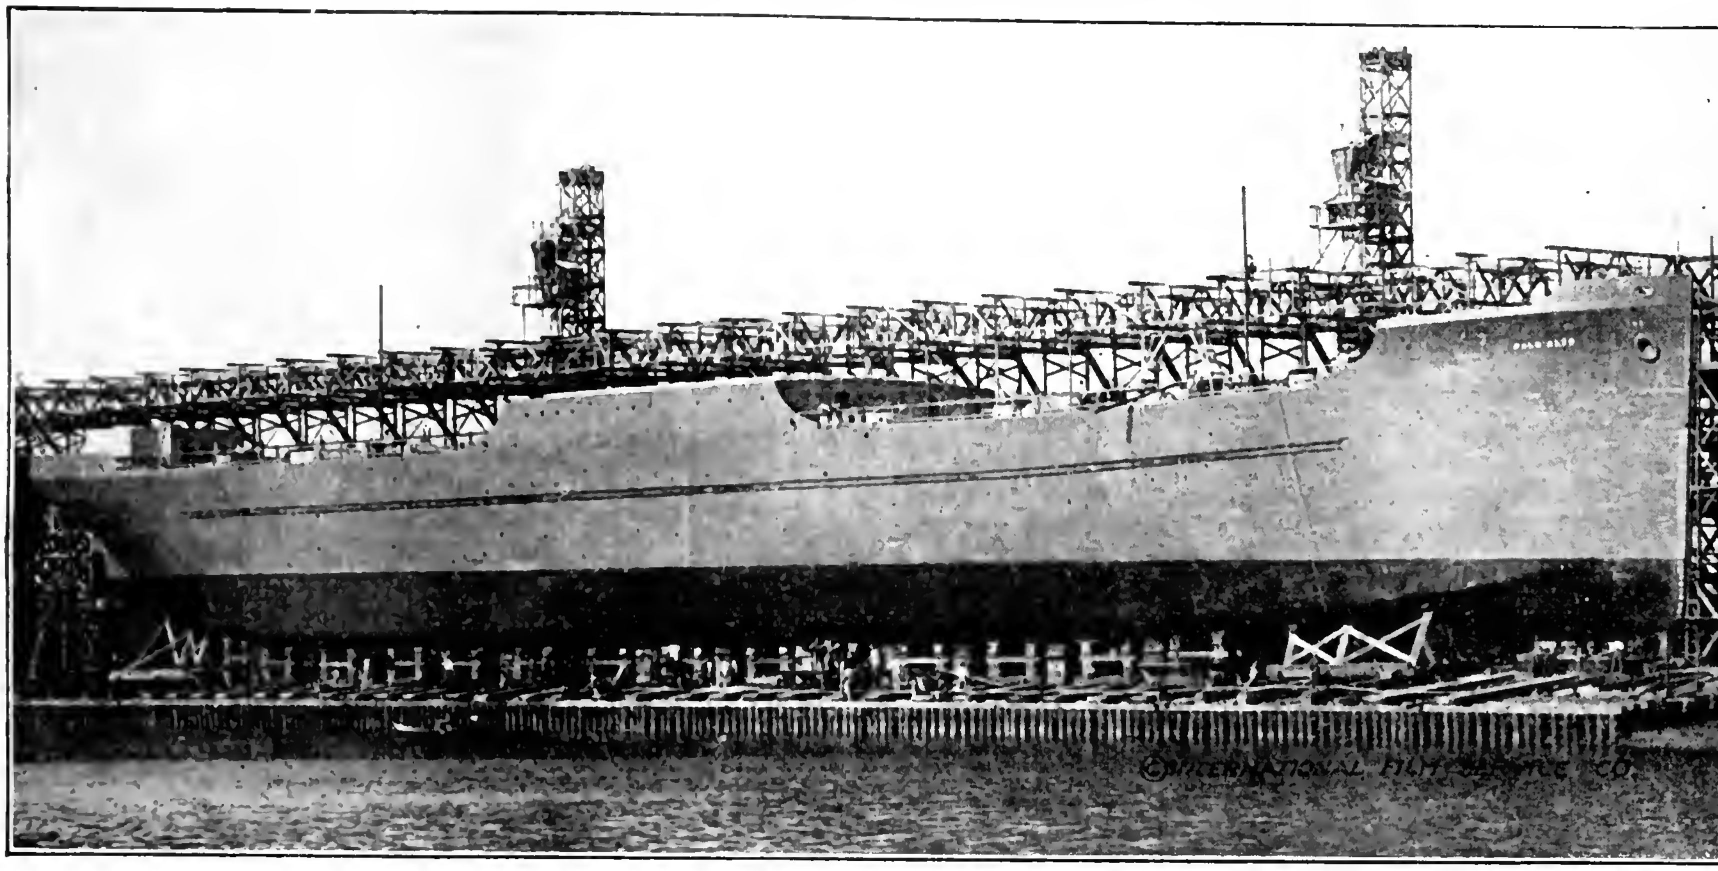
First Iowa Road-Bond Vote Under New Law Favorable

As a result of the favorable vote, June 3, on a $1,500,000 bond issue, the entire primary road system of Black Hawk County, Iowa, consisting of 84 miles, is to be paved. Black Hawk, in which Waterloo is situated, is the first county to hold an election under the new law. The fact that Iowa roads have been practically impassable this spring is reported to have had its effect on the vote.

Combined Dues Plan Operative

The Cleveland Engineering Society has approved the proposal that there be a reduction in the combined dues of members of the Cleveland Engineering Society and the American Society of Mechanical Engineers. The governing board of the latter body had already approved the plan, so it is now operative.

Largest Concrete Ship Launched at San Francisco



7500-TON CONCRETE OIL TANKER LAUNCHED SIDEWAYS AT SAN FRANCISCO MAY 29

The first of the Government's 7500-ton reinforced-concrete oil tankers, the largest concrete vessels ever attempted, was launched May 29 from the Government Island yard of the United States Shipping Board, on San Francisco Bay. The vessel was launched 90% complete and was put in 94 days after the date of the first concrete pouring. The actual pouring of the concrete was completed in about two weeks. The vessel's dimensions are: Length, 435 ft.; beam, 54 ft.; depth, 36 ft. The design was described in *Engineering News-Record* of Nov. 28, 1918, p. 986. R. J. Wig, chief of the concrete division of the United States Shipping Board, was present at the launching and Mrs. Wig christened the ship, which has been named "Palo Alto."

New State Highway Engineer Appointed by Kansas Commission

Appointment of a new state highway engineer has been announced by the Kansas Highway Commission. He is M. W. Watson, who has served as acting state highway engineer since July 15, 1918, in the absence of W. S. Gearhart in Army service. A large amount of road construction is in progress and more is planned, which will be directly under the supervision of Mr. Watson.

Before entering the service of the state, Mr. Watson practiced engineering in connection with coal mining, railroad work and municipal work in southeastern Ohio. He also served in the civilian branch of the United States Army in connection with the improvement of the Ohio River. For five years previous to entering the service of the Kansas Highway Commission as road engineer, in 1917, he served with the Illinois State Highway Department. He is a graduate in civil engineering from the Ohio State University.

Semi-Annual Meeting of Chemical Engineers

At the 11th semi-annual meeting of the American Institute of Chemical Engineers, to be held at the Hotel Lenox in Boston, June 18-21, a symposium on electric furnaces is planned for practically the whole of the opening day. Moving pictures of the operation of the furnaces are to be shown. A symposium on the registration of chemists will be held, and on the last day of the meeting the textile mills in Lawrence will be visited.

May Shipbuilding a New Record

Deliveries of completed ships in May passed all previous records, according to figures made public by J. L. Ackerson, vice-president of the Emergency Fleet Corporation. Moreover, for the first time since the beginning of the corporation's work deliveries exceeded launchings. Diminution of ship production in the early future is indicated by the fact that, considering steel construction only, fewer keels were laid than hulls launched or vessels delivered during the month.

During May, 136 ships totalling 768,025 dead-weight tons were delivered, completed, as against 111 ships of 543,720 tons in April. In both months the largest part of the tonnage was made up of steel ships, of which 87 (594,425 tons) were delivered in May, and 76 (423,320 tons) in April. The launchings for the two months were: May, 137 vessels (including 82 steel) of 705,958 tons; April, 118 vessels (including 74 steel) of 586,266 tons. Keel-layings amounted to 80 (all steel) in May, and 84 in April (including three wood), but the tonnage represented by these keels is 12% larger for May than for April.

Hurley Gives Average Cost of Shipbuilding

Gross Cost, Excluding Plant Extension and Housing Is Further Reduced by Profit Tax Payments

Shipbuilding cost figures for the vessels under construction by the Emergency Fleet Corporation were presented to the public during the past week, for the first time. In a published letter to Representative James W. Good of the House Appropriations Committee, Chairman Edward N. Hurley of the Shipping Board gives the net cost of the Fleet Corporation's ships at about $180 per ton.

In all, Congress has authorized the appropriation for shipbuilding purposes of $3,671,000,000, but of this only $2,625,451,000 has actually been appropriated. The board will require $673,368,301 additional, making a total ultimate expenditure of $3,298,819,301. Of this sum, a total of $202,853,456 should be charged off as representing not the cost of completed ships, but the loss involved in canceling contracts for 754 ships (which would have cost $797,564,276 to complete). Furthermore, shipyard plant extensions, shipworkers' housing and transportation costs amounted to $189,210,275, which is not a direct shipbuilding cost. Similarly, the administration cost of the board and the Fleet Corporation, amounting to $35,000,000, is not to be charged

against the ships. Thus, a total deduction from the gross expenditure should be made in the amount of $437,063,731, leaving the actual money spent for ships $2,861,755,570. This represents the construction of 2434 vessels aggregating 13,885,106 dead-weight tons, the ships thus averaging 5700 dead-weight tons carrying capacity and a cost of $1,175,000, or $206 per dead-weight ton.

As an offset against this cost Mr. Hurley cites the large income and excess profits taxes paid by shipbuilders on the profits of ship construction. Some shipbuilders, he says, have paid such taxes to the amount of $40 per ton; he estimates $25 a ton as the average tax payment of this kind by all shipbuilders, which indicates that very large profits were made by the yards. As far as the Government account is concerned, he reckons this $25 a ton as a deduction which, however, should still further be increased by the taxes paid by the many concerns that supplied steel, boilers, engines and other ship equipment, the amount of these taxes not being known. He concludes that, deducting $25 from $206, the balance of about $180 per ton is an outside figure for the actual cost to the Government of the Emergency Fleet Corporation's ships.

Southern Asphalt Association Formed by Contractors

The Southern Asphalt Association, comprising the principal public-works contractors engaged in laying asphalt pavement in the South Atlantic states, on June 1, opened offices in Atlanta, in the Healey Building. The association will be conducted in the interest of the construction of asphalt roads and pavements in the South Atlantic states.

The following officers have been elected: President, Walter Ely, of the Ely Construction Co., Augusta, Ga., and vice-president, W. R. Mayrant, general manager of the Simmons-Mayrant Co., Charleston, S. C. J. M. Woodruff, who resigned recently as manager of the advertising and paving department of the Standard Asphalt & Refining Co., of Chicago, is general manager.

Propose 385-Foot Concrete Arch

Tentative plans for a bridge across the Willamette River at Oregon City, prepared by the Oregon State Highway Department, show a main crossing consisting of a concrete and steel arch of about 385 ft. clear span, with a 120-ft. rise, flanked by reinforced-concrete approach spans, the entire structure being about 1000 ft. in length. According to a statement just issued, it is contemplated using in the main span a fabricated structural steel rib incased in a protective coating of concrete. In one of the drawings the approaches are of a Roman-arch viaduct type; that is, with multiple arches in vertical elevation. The bridge has been designed by C. B. McCullough, state highway bridge engineer, under the direction of Herbert Nunn, state highway engineer.

Second Pan-American Commercial Conference Meets

Necessary Action to Produce Closer Coöperation Discussed—Bearing of Engineering Considered

A commercial conference of the Pan-American countries was held in Washington, D. C., June 2-6, for the purpose of producing closer commercial relations among the various American countries. Many addresses were made in advocacy of better lines of communication and better commercial relations, and emphasizing the trade opportunities in South America. The afternoon of June 5 was devoted to the discussion of "Engineering and Its Significance and Relation to Commercial Developments."

William C. Redfield, secretary of commerce, in addressing the conference, announced that he had recommended to the United States Shipping Board the establishment of two new trade shipping routes to South America, one along the eastern and northeastern coasts, the other along the northern coast. He stated that these would serve to provide intercommunication among the South American countries as well as to carry American commerce. The Chilean ambassador, Señor Don Beltram Mathieu, called attention to the necessity for firm commercial ties as a means of building up sound diplomacy. He declared that the security of justice, of good order, of good faith in the observance of agreements are as indispensable as cheap production, transportation or credit. The Bolivian minister, Señor Don Ignatio Calderon, emphasized the need of South America for North American capital to develop its resources. In speaking of Mexico, Speaker Gillett of the House of Representatives laid stress upon the production of better conditions in Mexico as an essential to the best interests of all the American countries and of greatest interest to Mexico herself.

Chairman Edward N. Hurley of the United States Shipping Board aroused great interest while explaining the plans of the board to develop better shipping facilities to South America. Many questions were asked, and he stated that an initial trip is proposed for about Nov. 1. He assured the audience that no country would be neglected in the program, which would be developed for the best interests of all.

The engineering session was presided over by H. C. Parmelee, editor of *Chemical and Metallurgical Engineering*, and the session considered railways, highways, aërial tramways, light railways, and sanitation.

The railway discussion was introduced by Percival Farquhar, of New York, who devoted himself to a broad consideration of the question. Charles F. Lang, of Cleveland, Ohio, sent a paper on light railway transportation systems. Charles Whiting Baker, consulting editor of *Engineering News-Record*, New York, presented the subject of highways, and indicated their importance as railway feeders when arranged as systems radiating from railway stations. Dr. Walter C. Kretz, of New York, spoke on the use of the aërial tramway systems, pointing out the fundamental limitations of transportation with such methods and the conditions under which they might be constructed with profit.

The subject of irrigation and its relation to economic development was discussed by C. W. Sutton, of New York. The need for agreement on a number of technical engineering ideas now expressed in different Latin-American countries by a variety of words was brought out by V. L. Havens, editor of *Ingenieria Internacional.* Maj. George A. Soper, Sanitary Corps, U. S. A., advocated a definite plan to be adopted by municipalities in their program for community sanitation.

The principal proposals of the conference may be summarized as follows:

1. Immediate establishment of abundant freight, mail and passenger steamship facilities between the United States and Latin America.

2. Making of every effort by both governments and individuals to develop thorough reciprocity and mutual coöperation.

3. Meeting of the unavoidable and pressing financial needs of the Latin American governments and legitimate private undertakings, and also the protection and enlargement of the United States-Latin America trade.

4. A well defined program for the protection of the patents, trade-marks and copyrights of each country in all the other twenty countries.

5. Making of the parcel post beneficial alike to the United States and Latin American peoples, through the removal of unnecessary restrictions and regulations.

6. Improvement in the administration of the consular services.

7. Undertaking, without delay, all over Latin America, of extensive railway and highway construction.

8. Better credit facilities for Latin American buyers, closer study of Latin American trade, and the extension of United States banking connections.

9. Improvement and extension of news and commercial intelligence service.

The discussions will appear in English in the proceedings of the Pan-American Commercial Conference soon to be published by the Pan-American Union. The papers read at the engineering session will appear in Spanish in the July number of *Ingenieria Internacional.*

Lack Material for Economical Road Construction in Texas

With large amounts of money appropriated and the material plants in Texas working now at full capacity, there are insufficient aggregates in the state to carry on road work in an advantageous manner, according to R. J.

Windrow, state highway engineer. It is asserted that there are not over five quarries and 15 gravel pits operating that can deliver materials in large quantities. If it were not for local materials the outlook in the state would be discouraging.

Materials are plentiful in the state, according to the engineer, but capital seems unwilling to invest in plant equipment. Already the counties of the state have voted about $50,000,000 in bonds, with $22,000,000 more pending, the Federal Government has allotted $16,000,000 in Federal aid, to which the State Highway Department will add $2,800,000, and a constitutional amendment authorizing $75,000,000 for road purposes will be voted on in the autumn.

The highway department believes that the material business should be profitable, considering these large amounts of construction.

Commerce and Engineering Colleges Merged in Cincinnati

It is officially announced by the University of Cincinnati that the College of Commerce has been merged with the College of Engineering, under Dean Herman Schneider. Beginning next autumn a five-year coöperative course in commerce and administration will be offered. This course is planned to meet the demand for men trained both in the production and the commercial sides of business enterprises.

Dean Schneider thus describes the new course:

"The general plan is the same in detail and operation as in the coöperative course in engineering—that is to say, students will work alternating biweekly periods at practical work in business concerns and theoretical work in the university.

"The practical work during the first year will be in certain carefully selected departments of production, in the shipping departments of large concerns, in the traffic departments of railroads, and in the planning departments of factories.

"The work will cover a period of about 2½ years, after which the student will be transferred to the commercial side of business for the next two and a half years."

Enormous Increase in Exports

April exports passed the previous high record by nearly $100,000,000, according to a report issued by the Bureau of Foreign and Domestic Commerce, Department of Commerce. The figures given for exports and imports are as follows:

Exports	
January, 1919	$623,000,000
March, 1919	605,000,000
April, 1918	501,000,000
April, 1919	715,000,000
Past 10 months	5,705,000,000
Similar period 1918	4,844,000,000
Imports	
April, 1919	273,000,000
March, 1919	268,000,000
April, 1918	279,000,000
Past 10 months	2,474,0000,00
Similar period 1918	2,362,0000,00

Engineering Educators to Meet

At the annual meeting of the Society for the Promotion of Engineering Education to be held at Johns Hopkins University, Baltimore, Md., June 25-28, each half day's session will be devoted to some special topic, as follows:

At the first session, report of a special committee on the Mann report of the Joint Committee on Engineering Education; also papers on the "Case System for the Study of Law" and "Mental Tests for Engineering Students." At the second session, symposium on the effect of war on engineering education, opened by Anson Marston, dean of Iowa State College, also a paper on "The Unconscious Plagiarist," by G. I. Mitchell of the University of Pittsburgh. At the third session, military training in engineering schools, introduced by Col. W. S. Morrow, and by President Charles S. Howe of the Case School of Applied Science. At the session Friday morning the past and future of the society will be discussed by George R. Chatburn, past president, and in the afternoon the United States Naval Academy and Engineering Experiment Station at Annapolis will be inspected. At the last session there will be a symposium on changes in engineering courses, introduced by Dean Gardner C. Anthony, Tufts College, who will speak on the new course at that institution.

Protest Against Fishing in Water-Supply Reservoirs

Members of the New England Water-Works Association, called together on short notice, held a conference in Boston, recently, to discuss measures for opposing the passage of a bill which would make it lawful to fish in ponds used for water-supply in Massachusetts. Letters were prepared to be sent to all water boards in the state.

Civil Service Examinations

California.—Civil engineer, grade IV, $2700 to $3900 per year; examination in Sacramento, San Francisco and Los Angeles as soon after June 14 as possible. File applications with State Civil Service Commission at Sacramento before June 14.

California. — Construction engineer (civil engineer, grade III), $2100 to $2700 per year; examination in Sacramento, San Francisco and Los Angeles, June 20. File applications with State Civil Service Commission at Sacramento before June 14.

California.—Civil engineer, grade II, $1500 to $2100 per year; examination in Sacramento, San Francisco and Los Angeles, June 20. File applications with State Civil Service Commission at Sacramento before June 14.

California. — Senior engineering draftsman, grade II, $1500 to $2100 per year; examination in Sacramento, San Francisco and Los Angeles, June 20-21. File applications with State Civil Service Commission before June 14th.

New York.—Heating and ventilating engineer, office of state architect, $1500 to $2500 per year, June 28, apply to State Civil Service Commission at Albany for application forms before June 16.

United States

For United States civil service examinations, listed below, apply to the United States Civil Service Commission, Washington, D. C., or to any local office of the commission, for form 1312.

Senior engineer and senior architect, Interstate Commerce Commission, $1800-$2700 per year, June 10. File application before June 10.

Assistant designing engineer, Naval Ordnance Plant, South Charleston, W. Va., $9.20 per diem. July 8. File applications before July 8.

Valuation engineer, $3600-$4800 per year, and assistant valuation engineer, $2500-$3600 per year; technical staff, income-tax unit, Bureau of Internal Revenue, Treasury Department. No date specified.

Master computer, $2400 to $1800 per year, computer (Grade I) $1800 to $1400 and computer (Grade II) $1400 to $900, Ordnance Department. Applications will be received until further notice.

Assistant inspector of engineering material (aircraft), $5.92 per diem, July 15. File applications before July 15.

Engineering Societies

Calendar

Annual Meetings

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, 29 W. 39th St., New York; June 16-19, Detroit.

AMERICAN SOCIETY OF CIVIL ENGINEERS; 29 W. 39th St., New York; June 17-20, St. Paul-Minneapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS; University of Pennsylvania, Philadelphia; June 24-27, Atlantic City, N. J.

AMERICAN CONCRETE INSTITUTE; 6 Beacon St., Boston; June 27-28, Atlantic City, N. J.

The San Francisco Association of Members of the American Society of Civil Engineers held a meeting May 26 which was devoted to considering the work of the Committee on Development. Four committees had previously been appointed, each assigned to one of the four subjects given to subcommittees of the Committee on Development, and the reports of these four committees were printed and sent to members of the San Francisco Association, so that all might be prepared

to pass on the recommendations of the several committees. To expedite matters, each of the four committee chairman was made chairman of the meeting pro tem, during the discussion of the report of his committee. These men were Edwin Duryea, subcommittee No. 1; C. J. Rhodin, subcommittee No. 2; C. E. Grunsky, subcommittee No. 3; George L. Dillman, subcommittee No. 4. There was a lively discussion, which considered the subjects from many angles and served to provide H. L. Haehl, the association's delegate to the Committee on Development, with a comprehensive idea of the members' viewpoints. A stenographic report of the discussion was taken for reference.

The Colorado Association of Members of the American Society of Civil Engineers will hold its annual meeting at the Shirley Hotel, Denver, June 14. The regular business of this meeting, such as the election of officers, hearing the president's annual address, and reports of the various officers, will be taken up. In addition, there will be an address by E. A. Moritz, engineer, United States Reclamation Service, on "A Public-Works Department for the Federal Government." The usual informal dinner will precede the meeting.

The Rochester, N. Y., Society of Technical Draftsmen will hold its annual meeting and election of officers at its rooms in the Sibley Block, 328 Main St., East, on June 26, 1919. Among the addresses will be one entitled "Some Experiences in Construction Work in the Tropics," by Leslie S. Wood, of the Eastman Kodak Company.

The Houston Engineers' Club and local members of the American Association of Engineers held a joint meeting May 26 at which C. E. Drayer, national secretary of the association, explained its principles and work. Officers of the club asked for a proposal under which it might become a part of the association. The club is one year old and has one hundred members, the number of engineers in its district being three hundred. In a discussion on licensing, J. M. Howe stated that an effort would be made to have a law passed at a special session of the legislature which meets this month. Maj. J. A. Rossiter suggested that the club direct the formation of a city-planning commission. A plan will be the subject discussed June 12. J. C. McVea, city engineer, is president of the club.

The Southwestern Society of Engineers held a convention at El Paso, Tex., on May 29-31, 1919, at which topics of general interest to engineers were discussed. Among the addresses and speakers were: "Oil Geology," by G. M. Butler, dean of the School of Engineering, University of Arizona; "Licensing of Engineers," by C. E. Drayer, secretary of the American Association of Engineers, of Chicago; "The Concrete Ship," by C. E. Barglebaugh, former engineer, Emergency Fleet Corporation, and "Modern Wireless Telegraphy and Telephony," by R. W. Goddard, in charge of the school of radio engineering, New Mexico Agricultural and Mechanical College. The officers for the previous year were reëlected.

The Rochester, N. Y., Engineering Society will hold its annual meeting June 13, 1919, at the Hotel Seneca. This will be the last get-together meeting of the season. An informal dinner at the Hotel Seneca will be followed by the election of officers and committee reports, and by an address by J. Y. McClintock, superintendent of highways, Monroe County, on "The Finger Lakes Road Project and the Roosevelt Road."

The Associated Engineering Societies of St. Louis held a joint meeting at the Engineers' Club, under the auspices of the St. Louis Section of the American Society of Mechanical Engineers, June 5. Wallace C. Capen, St. Louis manager, the White Co., gave a talk on "Certain New Developments in Rear Axle Construction." Motion pictures and lantern slides of motor-truck performance in Mexico and France were shown.

The Canadian Society of Domestic, Santiary and Heating Engineers held its annual convention at Montreal June 4-5, 1919. Reports were presented concerning the laws regarding plumbing and sanitation in the various provinces, with the object of formulating model laws to regulate these matters. The following officers were elected: President, F. R. Maxwell, of Toronto; secretary, G. F. Frankland, of Toronto.

The Louisiana Engineering Society held its regular meeting in the library room of the State Museum Building, New Orleans, June 9, 1919. Among the addresses was a paper by Thomas L. Willis on "Garbage Disposal."

Personal Notes

E. C. EARLE, designing engineer, Bureau of Public Works, Manila, P. I., has been appointed chief designing engineer of the bureau and is now engaged in carrying out the design and construction of a new ocean terminal pier and the enlargement and alteration of several of the older structures at the port of Manila.

C. C. THOMAS, formerly sales engineer of the Denby Motor Truck Co., has been appointed chief engineer of the Fields Manufacturing Co., Owosso, Mich. Mr. Thomas has been identified with several branches of work in the automotive industry, being successively in the experimental engineering department, service manager and sales engineer.

MAJ. THOMAS G. HAMILTON, formerly a construction engineer at Gary, Ind., who has been a member of the general staff of the American Expeditionary Forces, has been promoted to the rank of lieutenant colonel and has received the decoration of the Cross of the Legion of Honor from the French Government. He expects to return to Gary in July, upon his release from the service, and resume his work with the T. G. Hamilton Construction Company.

DAVID MACNAUGHTON has opened a consulting engineering office at 528 Lincoln Life Bldg., Fort Wayne, Ind., for the practice of industrial engineering, including the making of illumination surveys, valuations, reports and rate investigations of electric light and power companies. Mr. MacNaughton has been engaged in public utility engineering for the past 12 years for large companies operating in Indiana, Illinois, Michigan, Ohio and Wisconsin. He has also had wide experience in valuation work, making reports and analyzing rate charges for electric light and power service.

P. B. MCDONALD, who has been head of the department of engineering English at the University of Colorado for the past two years, has been appointed assistant professor of English in the engineering college of New York University.

H. F. HARMON and J. H. SLUSS, of Graham, Va., have formed a partnership and will carry on the construction work formerly handled by the J. H. Sluss Construction Co., of Graham, Va., and Huntington, W. Va. Mr. Harmon has had long experience in the construction business, as superintendent and manager of large construction companies, while Mr. Sluss is a civil engineer with varied construction experience, particularly in railway construction.

B. H. FRASER, formerly assistant chief engineer of the Department of Marine, Ottawa, Canada, has been appointed chief engineer, succeeding COL. WILLIAM P. ANDERSON, retired.

W. J. KRULL, HOWARD T. KRULL and HOMER B. GRADLE, of Hobart, Ind., have organized a construction company, to be known as the TRIANGLE CONSTRUCTION CO., with offices in the American Trust & Savings Bank Building. They will both make plans as architects and do construction work.

ERNEST P. GOODRICH, consulting engineer, announces the removal of his office to 140 Nassau St., New York City.

HOLLIS LIBBY, county surveyor of Lane County, Oregon, has resigned to accept a position as engineer with the State Highway Commission. Mr. Libby has served as county surveyor for the past six years, with the exception of the past nine months, while he was in the Army service.

PAUL SUMMY, city engineer of Warsaw, Ind., has resigned to devote his entire time to his business interests.

P. F. WHITTIER has resigned as engineer for the Whittier Mills Co.,

Chattahoochee, Ga., to accept the position as assistant to the State Highway Engineer, W. R. NEEL. He will take charge of the excess War Department equipment allotted to Georgia for Federal-aid highways.

LIEUT. COL. ARTHUR H. PARKER, of Cody, Wyo., who has recently returned from overseas service with the Quartermaster Corps of the 32nd Division, has been appointed assistant engineer, State Highway Department.

A. W. MOSELEY, of Kansas City, Mo., has been appointed by Col. E. M. STAYTON as his assistant in building the road system of Clay County, Missouri.

G. SYVERSEN and C. KRUSE, New York City, severed recently their connection with the ROBINS CONVEYING BELT Co., and sailed, June 9, for Christiania, Norway, where they will form a partnership to practice industrial engineering They will also represent the company in Norway.

T. R. SPENCE, formerly with the engineering department of the Army, has been appointed by the State Highway Department as superintendent of the surplus Federal equipment allotted to the State of Texas for Federal-aid road work.

CAPT. RICHARD SCHERMERHORN, of New York, of the Engineering Section, Sanitary Corps, American Expeditionary Forces, has received his discharge from the service and has resumed his practice as landscape architect and civil engineer at 363 Lexington Ave., New York City.

CHARLES CURRY, Kansas City, Mo., who served as a lieutenant with the 110th Engineers in France, has been appointed assistant city engineer of Kansas City, Mo. Before entering the service he was assistant in the sewer-engineering division of the city.

COL. E. M. STAYTON, of the 110th Engineers, has received his discharge from the service and has been engaged by Clay County, Missouri, to supervise building of its road system. Colonel Stayton was formerly highway engineer for Jackson County, Missouri.

CAPT. J. H. BONNER, Engineers, U. S. A., has received his discharge from the service and has been appointed chief engineer of the Montana Railroad and Utility Commission, Helena, Mont. Before entering the service Captain Bonner was a member of the staff of the College of Engineering, University of Montan

TAYLOR A. BORRADAILE, of Charleston, W. Va., has been appointed city chemist, and will take charge of the chemical and bacteriological research department of the city government. For the past two years he has been with the chemical department of the Warner-Klipstein Chemical Co., of South Charleston.

FRANK E. BAKER, engineer in charge of construction for Methodist Episcopal projects in Europe and North Africa, left, June 5, for France to begin work on the 11 towns of the Chateau-Thierry battlefield which have been assigned to the Methodist Episcopalians foi reconstruction. He will supervise a five-year building program, which will include the erection of sixty permanent buildings in France and about the same number in Italy.

H. H. ESSELSTYN, commissioner of public works of Detroit, Mich., has resigned, to take effect June 30, to return to the firm of ESSELSTYN, MURPHY & HANFORD, engineers and architects, 810 Marquette Building, Detroit. His resignation was made necessary by the increased scope of the work of the company

H. H. FILLMORE, formerly resident engineer with the Los Angeles, Calif., Highway Commission, has been appointed district engineer in charge of the Los Angeles office of the Portland Cement Association, in the Merchants' National Bank Building. He will have charge of the association's activities in Southern California and Arizona.

HERBERT J. FLAGG, Coast Artillery, U. S. A., has recently received his discharge from the service and has returned to his former position as assistant engineer, Public Service Commission of the State of Washington, at Olympia, Wash.

LIEUT. C. B. LEWIS, recently discharged from command of Co. C, 217th Engineers, has accepted a position as sales engineer with the Northwestern Expanded Metal Co., of Chicago. Before the war he was superintendent with Albert Kahn, architect, of Detroit.

J. R. ROBERTS has been appointed chief engineer of the Central Illinois Public Service Co., with headquarters at Mattoon, Ill.

O. B. KERCHER, formerly assistant to D. MOOMAW, county road engineer of St. Josephs' County, Indiana, has resigned to join the forces of the Indiana State Highway Commission.

LIEUT. COL. AMOS A. FRIES, Engineers, U. S. A., who was a brigadier general in charge of the Chemical Warfare Service of the American Expeditionary Forces, has been made a Commander of the Legion of Honor by the French Government.

CHARLES F. O'HAGAN, formerly chief engineer of the William B. Scaife & Sons Co., Pittsburgh, has been appointed resident engineer and manager of the Chicago office of the company, at 38 S. Dearborn Street.

JAMES W. TOWNSEND has opened an office at 709 Empire Bldg., Detroit, Mich., for practice as a designing and construction engineer. He is at present building a theater at River Rouge, Mich.

JOHN H. BRINGHURST, associate professor of civil engineering, Johns Hopkins University, has accepted the position of dean of the faculty and professor of engineering design at the Drexel Institute, Philadelphia. Professor Bringhurst is a graduate of the University of Michigan, and since graduation has had a varied experience in structural engineering. He has been associated with Johns Hopkins University since the autumn of 1916.

HENRY B. SEAMAN, supervising engineer, Navy emergency plant extensions, Bureau of Yards and Docks, terminates his connection with the bureau June 15. While with the bureau Mr. Seaman has had general supervision, under Admiral Rousseau, of construction work at 35 shipbuilding and accessory plants throughout the country. The work supervised has cost more than $55,000,000. Mr. Seaman was formerly chief engineer of the New York Public Service Commission, First District. He will return to New York, and his temporary address will be 363 Grand Ave., Brooklyn, N. Y.

E. J. TESKEY, of South Bend, Ind., has been appointed assistant to D. MOOMAW, county road engineer of St. Joseph's County, Indiana, with office in South Bend.

C. J. RENNER, of Mount Vernon, N. Y., has been appointed city engineer of Ellwood City, Penn., succeeding ALEXANDER MAINES, who has resigned.

FRED G. SIMMONS and JOHN C. DAVIS have formed a partnership as consulting engineers, with offices at 811 Majestic Building, Milwaukee, Wis., for the carrying on of a general engineering business. Mr. Simmons was formerly commissioner of public works of the City of Milwaukee and engineer of construction and maintenance for the Milwaukee Electric Railway & Light Co. Mr. Davis was dean of the College of Applied Science and Engineering at Marquette University and director of the Bureau of Municipal Research of the City of Milwaukee.

OBITUARY

FREDERIC A. BIGGI, highway contractor and civil engineer, of Albany, N. Y., died in that city, May 31. He was graduated from the Massachusetts Institute of Technology in 1904, and was connected with work for the Public Service Commission, First District, New York State Barge Canal, and New York State Highway Department for a number of years. For the past four years he was engaged in the construction and repair of highways.

EDWARD F. MULLANEY, an assistant engineer in the city engineering department of Minneapolis, Minn., died in that city, May 21, at the age of 64. He had been in the service of the city for the past 34 years.

Corrugated-Iron Manhole Sand-traps for Tile Drains

A new form of corrugated-iron combination manhole and sand-trap, for use in tile drainage on irrigation work and elsewhere, was described by L. E. Thompson, irrigation expert, in the June issue of the *Highway Magazine*. This method of access to the underdrainage system is formed by joining convenient-sized sections of circular corrugated-iron pipe. Many desirable features of this device are mentioned by the writer; some of them are as follows:

COMBINED MANHOLE AND SAND-TRAP

Combination manhole and sand-traps, extending about 1 ft. below the drains, serve as a settling basin for any sand or silt which may pass through the pipe; provision can always be made for flushing the drain, which is an important feature; the sizable opening at the top provides a means for operating a root-cutting or drain-cleaning device; and the manhole may be utilized to carry off surface water, thus serving a double drainage purpose.

The device as described by Mr. Thompson is about 10 ft. deep, 2 ft. wide in the neck, 4 ft. at the bottom and made of "Armco" pipe. An iron top is provided, as shown in the cut, and the device can be supplied with or without an iron bottom.

Good Roads Show and Exposition To Be Held in South Carolina

The Southeastern Good Roads Show and Agricultural Implement and Tractor Exposition will be held at Greenville, S. C., July 14-19, 1919. In addition to addresses by prominent road officials and highway transportation enthusiasts, there will be a complete exhibit of all kinds of roadbuilding and agricultural implements and machinery. The general manager is F. M. Burnett, of Greenville, S. C.

Large Weld Repairs Stern Frame of "Northern Pacific"

Welding of the large stern frame of the U. S. A. transport "Northern Pacific," which was broken just above the rudder lug when the steamer went upon the beach off Fire Island, New York, last January, has been accomplished by the Metal & Thermit Corporation, of New York. The section welded was entirely broken through as a result of the severe strain when the boat went aground with its load of homeward-bound troops.

The weld required 1400 lb. of thermit for the production of the necessary amount of molten metal, and the operation was performed without removing the casting from the ship. This obviated the delay and expense which would have been entailed by the only alternative of purchasing an enormous new casting and installing it in the "Northern Pacific."

Business Notes

THE LEHIGH PORTLAND CEMENT CO., of Chicago, announces the appointment of C. B. Rogers as assistant treasurer and credit manager in place of W. E. Viets, who has resigned.

THE MASSEY CONCRETE PRODUCTS CORPORATION, Peoples' Gas Building, Chicago, announces the appointment of P. E. Longstreet as resident manager of the Western district, in charge of all sales in that territory. His headquarters will be at 925 S. 6th St., West, Salt Lake City, Utah.

L. V. ESTES, INC., industrial engineers and accountants, have removed their offices from the McCormick Bldg., to the Century Bldg., 202 S. State St., Chicago, Ill., where they will occupy the entire fifteenth floor.

THE STARK ROLLING MILL CO., of Canton, Ohio, announces the appointment of George W. Scott as district manager for the Chicago territory, with headquarters at 1119 Marquette Bldg. Mr. Scott was formerly Chicago representative of the Pittsburgh Steel Co. The company also announces the appointment of Thomas F. Murphy as district manager for the Canton, Ohio, territory. Mr. Murphy was formerly connected with the American Sheet & Tin Plate Company.

THE MANUFACTURERS' CO., of San Francisco, has opened an office at 811 Lumber Exchange Bldg., Chicago. B. F. Wade, formerly chief engineer of the Redwood Manufacturers' Co., now represents the company in the Chicago office.

THE AMERICAN BLUEPRINT CO., of Chicago, Ill., announces that Vernon T. Brauns, for the past four years salesman for the company, has been made manager. Mr. Brauns has been active in the American Association of Engineers and the Western Efficiency Society, and is well known among railroad valuation engineers for his promotion of a process for reproducing tracings for presentation to the Interstate Commerce Commission.

THE VAN DORN & DUTTON CO., of Cleveland, Ohio, manufacturers of gears and pinions for electrical work, has opened branch offices in New York and Chicago. Harry S. Keegan, formerly with the Chicago surface lines, will manage the Chicago branch, with offices at 1241 First National Bank Building. John Keegan, formerly with the Interborough Rapid Transit Co., of New York, will manage the New York office, which will be at Room 313, 30 Church Street.

THE DAYTON INSULATING DIE CO., U. B. Building, Dayton, Ohio, manufacturers of molded insulation products and dies for the same, has bought the Edgemont Die Castings Co., of Dayton, Ohio, and will consolidate it with its other plants, operating under a new name. E. A. Kurz will be president. A new plant, 60 x 120 ft., and two stories high, will be immediately erected at Edgemont, Ohio.

Trade Publications

The following companies have issued trade publications:

THE IRVING IRON WORKS CO., of Long Island City, N. Y.; catalog, 4½ x 8½ in., 36 pages, illustrated; descriptive of "Irving Subway Fireproof Ventilating Flooring."

THE BELMONT IRON WORKS, 22nd St. and Washington Ave., Philadelphia, Penn.; catalog, 14 x 8½ in., 16 pages, illustrated; an export catalog printed in three languages, English, French and Spanish; describes the plants and products of the works and gives weights and dimensions of various steel sections.

THE GENERAL FIREPROOFING CO., Youngstown, Ohio; pamphlet, 8 x 11 in., 16 pages, illustrated; gives data on waterproofings, damp-proofings and technical paints.

THE AMERICAN SPIRAL PIPE WORKS, Chicago, Ill.; catalog, 8 x 10½ in., 87 pages, illustrated; describes and illustrates the advancement in the manufacture of corrugated-steel furnaces, large-diameter lap-welded steel pipe, spiral-riveted pipe, forged-steel flanges, and forged-steel boiler nozzles.

THE ALLIS-CHALMERS MANUFACTURING CO., Milwaukee, Wis.; booklet, 5 x 8½ in., 61 pages, illustrated; describes the works and products of the company.

THE COREY MFG. CO., Marshfield, Ore.; folder, 3¾ x 6¾ in., eight pages, illustrated; describes the Corey banding tool for placing large wire bands around wood-stave or metal pipe.

THE CEMENT GUN CONSTRUCTION CO., of 900 S. Michigan Ave., Chicago; pamphlet, 6 x 9 in., 24 pages; illustrated; shows views of numerous structures built up by or covered protectively by the cement gun.

THE AMERICAN CEMENT MACHINE CO., INC., of Keokuk, Iowa; catalog, 8½ x 11 in., 9 pages, illustrated; describes "Boss" concrete mixers.

A Consolidation of Engineering News and Engineering Record McGraw-Hill Company, Inc.—JAMES H. MCGRAW, *President*

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING AND CONTRACTING

E. J. MEHREN *Editor*

CHARLES WHITING BAKER *Consulting Editor*

Volume 82 NEW YORK, THURSDAY, JUNE 19, 1919 Number 25

The Development Committee Speaks

MUCH food for thought is contained in the progress report of the Development Committee of the American Society of Civil Engineers submitted at Minneapolis this week and printed on p. 1229. The many recommendations which the committee offers as a tentative outline of its final report deserve the earnest consideration and full discussion which the committee desires. If these are given, as we trust they will be, crystallization of opinion may be expected that will go far toward putting the society and the whole engineering profession where they belong among the forces of twentieth-century technical and civic progress.

Across the Atlantic

NOT because it is a matter of news to anyone who reads this, but because it is a record in transportation history, it should be set down that on June 14-15, with Capt. John Alcock, an Englishman, as pilot, and Lieut. A. W. Brown, an American, as navigator, a Vimy-Vickers biplane made the first nonstop flight across the Atlantic, a voyage of 1930 miles from Newfoundland to Ireland in 16 hours and 12 minutes. Adventure though it was, the flight marks one more step forward in air navigation, not only as it testifies to the solid engineering background of the plane and its engine, but because of the unerring direction through sleet and fog and starless night straight to the big wireless station on the Irish coast.

New Pumping Engine Promised

RECIPROCATING pumping engines have been so far displaced by rotating types of late that no little interest was created by Mr. Decrow's paper on the "Unaflow" pumping engine read at the Buffalo water-works convention last week (p. 1193). The interest was heightened and the hope for an early placing on the market of the new machine increased by the working unit seen in operation at the local water-works. Proposed tests of this 3,000,000-gal. unit will be awaited with interest.

Machines Instead of Laborers

DRUDGERY is becoming unpopular in the world. The hewers of wood and drawers of water are more scarce than they were before the war decimated their numbers and educated to less tiring and irksome labor many that were spared. In this country especially, the effect is clear. The increased cost of unskilled labor has far surpassed the universal increase in cost of all things. Mechanics' wages have gone up 30, 40, and in a few cases 100% over pre-war standards. Common labor today costs two and three times what it did five years ago, and in most construction work, particularly in heavy construction, common labor makes up the bulk of labor costs. What is to be done? The answer is obvious. Machinery to supplant unskilled labor must be provided. Too much of the inventiveness of mankind has been devoted to reproducing mechanically the skill of man. More must in the future go to relieve the drudgery, and in so doing to reduce the cost of production and of construction. If the material-handling machinery men who met in New York City last week can, through the joint effectiveness of their machines and their propaganda, spread this gospel, their reward will be commensurate with the great service rendered.

Buffalo Should Save Still More Water

MARKED has been the reduction of water waste in Buffalo by pitometer surveys and house-to-house inspection. There can be no doubt of the wisdom of continuing work along both lines, but do not Mr. Andrews' own statements (p. 1196), that the good results of house-to-house inspection seem likely to disappear in two or three years, indicate that at most only local conditions can justify the postponement of universal metering in Buffalo? True, the plan is to install meters where most needed. True, also, that in a city where consumption and waste once reached the enormous figure of 339 gal. per capita wholesale metering cannot be instituted over night. Time for educational leaven to work is often necessary in such cases. Mr. Andrews' educational bulletins (see *Engineering News-Record* of June 5, 1919, p. 1094) and the pressing need for reducing consumption so as to make filtration possible at a reasonable outlay, combined with the transient results from house-to-house inspection, will doubtless quicken Buffalo's speed in metering.

Labor Opposed to Radicalism

DURING the war there was constant fear that the socialistic element in the American Federation of Labor would get the upper hand. In fact, there were surprising demonstrations of its strength. It appears, however, from the convention of the federation in session last week in Atlantic City, that this element has either been very largely eliminated or, coming to its senses, has realized that true progress lies along the lines that the federation has pursued for many a year. At Atlantic City the determination has been clear to stamp out anything that savors of the revolutionary doctrine or action. Such assurance is encouraging at the present time, though anyone who has followed the federation's activities knew that it could be counted on to oppose radicalism if the Gompers element remained in power. The fact that the federation will oppose revolutionary doctrine and methods, however, is not assurance of speedy adjustment of the labor phase of our industrial problem. But it does warrant the hope that we can go about the task of stabilizing our industries without the fear that there will be lacking the coöperation of the strongest factor in the labor field.

Useless to Postpone Construction

THE consensus of opinion at the convention of the American Water Works Association in Buffalo last week was that the present high level of prices will continue, with little downward change, so it will be useless to postpone construction longer for the sake of less outlay. Prices of some materials may fall, but since labor cost is bound to keep up or even increase, and because labor enters so largely into water-works materials and construction, there seems no hope of any considerable reduction in water-works costs. The vital importance of water-works upkeep and extension, coupled with the fact that this is a revenue-producing utility, adds strength to the argument for going ahead with much-needed water-works operations.

Coöperative Course in Commercial Engineering

THE departure by Dean Herman Schneider at the University of Cincinnati in inaugurating, through the merged College of Engineering and Commerce, a coöperative course in commercial engineering, is an epoch-making venture. Judged from the standpoint of need for such a course, which was announced in our news pages last week, its success can be predicated beforehand—business men have been clamoring for applied scientists who could also think in terms of commercial values. And while courses in which engineering and business training have been combined already exist in various institutions, this is the first in which the coöperative system is applied. With the great advantages of first-hand contact with commercial problems such as results from the coöperative principle, the effectiveness of the new course, especially in the experienced hands of Dean Schneider, can be assumed from the start. It seems not unlikely that this new departure will mean a slowly developing element in the profession which should help mightily in raising its status in the business world.

Building Activity and Mortgages

COMPLAINT has been general that the revival of building construction has been delayed because of the difficulty of getting mortgage money from insurance companies, savings banks and trust companies. The matter has come up for public discussion at New York in connection with an inquiry on the raising of rents. The insurance companies recently made their defense. They admitted that their building loans had been heavily curtailed, but maintained that that had been done in order that they might invest in Liberty Bonds. The Government's necessity, they contended, took precedence over the housing demand. The unfortunate part of the situation, however, is that with the signing of the armistice large funds did not become available immediately for building loans because the companies had subscribed on their credit and even now have large payments to make. Probably the investment situation of the savings banks and trust companies is similar. In that case the building field cannot expect a heavy supply of mortgage money until the fall. That funds will be made available as quickly as the institutions can divert them to mortgages seems probable, for the return is lower on Government securities. Of course, one may expect on long-term mortgages a demand for a higher security margin than in the past, due to the present high construction costs. In any event, judicious pressure should help hasten progress in the matter of building loans, for at New York the companies concluded, as a result of the discussions, that they could find some $30,000,000 of mortgage money. The thought is worth passing on to the many other communities faced with housing shortage. The situation is one "affected with a public interest," an angle that the controllers of the public's funds as accumulated in the insurance and savings companies are not slow to grasp.

Partial Government Ownership of Railroads in Canada

GOVERNMENT ownership and operation of a large portion of Canada's transportation system are to be carried out under the terms of the bill providing for the incorporation of the Canadian National Railway Co. to take over and operate the properties of the Canadian Northern System, passed by the Canadian Senate May 27, as noted in the news section of this journal June 5. The fact that the passage of the bill has caused little comment may be ascribed to its being a natural outcome, although but a partial solution, of Canada's railroad problem, which has been brought about by the previous riot of ill-advised construction and by extravagant public gifts and guarantees, supported on an unsound financial structure.

Briefly, it is provided that the Canadian National Railway Co. shall be incorporated, with a board of directors nominated by the Governor General in Council, to take over and operate the properties of the bankrupt Canadian National System. Any deficits or surplus earnings from the operation of the lines will be paid out of or accredited to the national treasury. The capital stock of the company is to be vested with the Minister of Finance. Opportunity is provided for the indefinite extension of Government ownership and operation of public utilities through the insertion of a clause providing for the transfer to the control of the Canadian National Railway Co. of "any railway company, or of any other company having corporate powers or properties which may be conveniently exercised or operated by the company," in which the Canadian Government may have acquired the controlling interest. It may reasonably be assumed that the clause is destined to be applied to the Government-financed National Transcontinental and the Intercolonial Lines.

A little over two years ago the Royal Commission, composed of Sir Henry L. Drayton, W. M. Acworth and A. H. Smith, appointed to investigate Canada's desperate railroad situation, rendered its report. The Drayton-Acworth report, which recommended the virtual taking over into Government ownership of the Grand Trunk, the Grand Trunk Pacific, the Canadian Northern, the National Transcontinental, and the Intercolonial Lines, is partly carried out under the terms of the present bill. The minority report of A. H. Smith—to retain private operation and ownership of the lines, dividing the business into definite geographical sections and distributing the physical properties among the companies accordingly—has evidently been flatly rejected. The alternate plan of W. F. Tye, previously chief engineer of the Canadian Pacific, recommended that all of the railroad lines in Canada, with the exception of the Canadian Pacific, be unified, so that there would be created a transcontinental system which would be a worthy competitor of the strong Canadian Pacific. As

expressed by this journal editorially (May 7, 1917, p. 370), the Tye plan seemed more commendable than either of the others. It now appears that it is likely to be carried out, although under Government ownership, through the provision of the bill which permits indefinite extension of the control of the new company.

We can find no parallel between the railroad situation in Canada and that in the United States. Canada's railroad troubles were at first brought about by ill advised expenditures for new construction and the founding of companies on shadowy financial bases, backed by Government guarantees. The result was inevitable. In this country, the vast majority of railroad properties are in sound financial condition, granting that many, previous to rental by the Government, were living from hand to mouth, due to the persistent refusal of the Interstate Commerce Commission to grant increases in rates sufficient to meet increasing operating expenses and give an adequate return on the investment. While Canada has been oversupplied with transportation and her railroad troubles started with unwise expenditures for capital account, the United States has been under-supplied, and its chief difficulties lie in ever-increasing operating expenses, with gross revenues insufficient to operate the lines and pay rental to the owners.

The United States should be keenly interested in the railroad situation in Canada, not only for the reason that its railroads connect with Canada's, are physically like them and are in competition with them, but also because Canada's participation in railroad ventures has not proved fortunate, and holds lessons for us in the railroad settlement we must soon undertake.

The American Water Works Association

WITH 7500 water-works to draw upon, besides engineers, chemists and bacteriologists in private practice and a thousand or more water-works manufacturers and contractors, the American Water Works Association attained some 1400 members at high-water mark. Its membership should be at least 5000. The recent slight decline in membership may be attributed to war conditions; otherwise it would be discouraging, as perhaps it is, anyway. The falling off in technical-committee work during the past few years may also be laid to war conditions in large part, but this does not seem to be the sole cause.

Whatever may have retarded growth in membership and committee work in the past, and kept the association from entering that larger field of usefulness to be expected from a national organization of water-works men, should not hold in the future. That members having the advancement of the association at heart feel this was evident at the Buffalo convention of the association last week. Official measures proposed for meeting the situation, or at least for increasing and holding the membership, were: (1) Publishing the *Journal* six instead of four times a year and continuing the recent practice of including a considerable number of original contributions; (2) organizing sections in each state where the membership is 20 or more. Budget provision was made for greater frequency of publication, and approval was also given to the use of original contributions. It would be hard indeed to argue successfully against either of the branches of the first proposal. The second proposition is also good so far as it goes, but a hard drive for additional members, and doing more than is now being done for the membership, for the water-works fraternity in general and for the country at large, are two great needs and duties of the association.

More members and more service should be the slogan. Service alone would do almost as well, for nothing would bring new members so fast and hold them so long as increased service to them, the interests they represent and the general public.

Additional members would bring increased income but how provide funds for the added service which is essential to gaining and holding members? One means is directly at hand. In recent years the association has not only made good a deficit but it has also created an "investment fund." This fund totals $13,000. It is proposed either to draw somewhat upon this fund, or lessen additions to it, for useful current work of immediate benefit to the members. This appears to be so wise a policy that it seems strange that it was not adopted earlier. If the *Journal* be made a more frequent and helpful visitor, the association would get and keep a stronger hold on its members. Then, if in addition to this a material increase could be made in the small sum appropriated for committee work, the association might expect to make rapid progress.

The need for more money for committee work seems to be forcibly illustrated by the position of the association in relation to the American Electrolysis Committee. The association's members of this committee seem to be handicapped for funds, as compared with the representatives of the other utilities on the committee. The peculiar and almost isolated position of the American Water Works Association in this electrolysis matter—most of the other utilities being in more or less close affiliation with the utility creating the electrolysis problem—makes it particularly desirable that the association be able to take a strong stand. To do this funds for its members on the joint committee are needed.

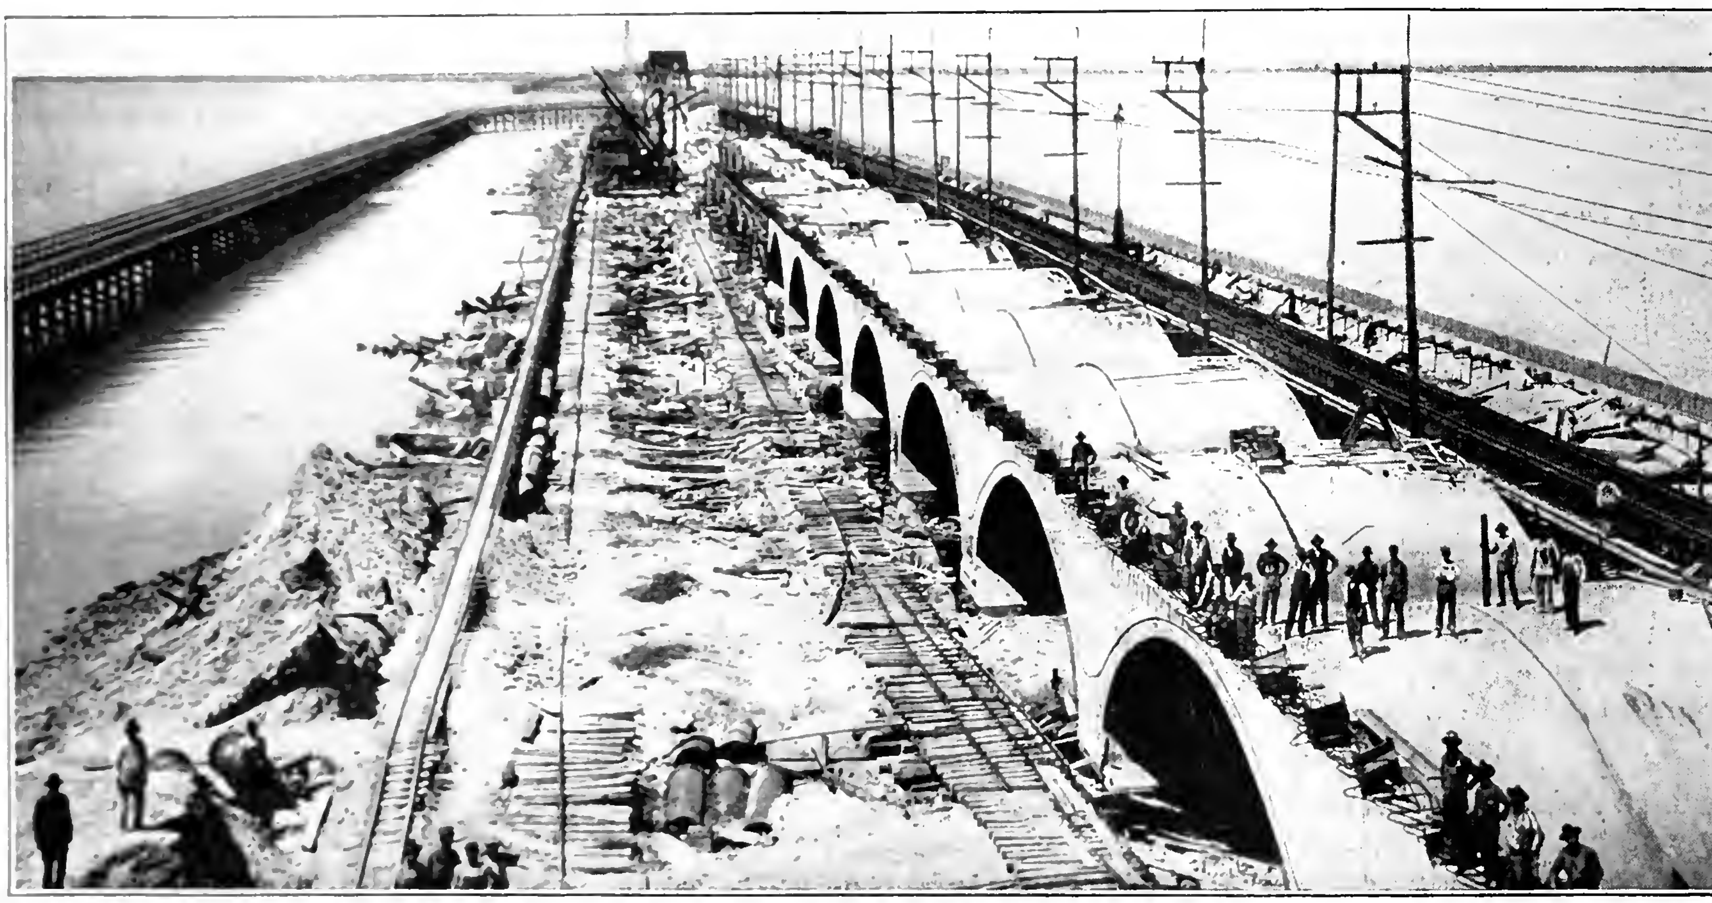
An unofficial proposal for promoting the association discussed at Buffalo was an increase in membership dues. This might strengthen the association in some respects, but it would tend to decrease the membership, or retard its rate of growth, and thus might pull down income. The members who dropped out and the prospective members kept out by higher dues need what the association has to give. Conceivably, they might be served by relatively low-priced membership in state sections, which would cover subscription to the *Journal*. Probably a rather high membership fee in the parent association would be necessary under a plan for local-section membership carrying with it receipt of the *Journal*. An extension of corporate membership, under which a city or water company joins the association, might help solve the problem of increased dues.

Finally, as has long been evident, what the association must come to, if it is to do its full duty, is to have one or more full-time officials. At the start a secretary-editor would do very well. Such an official, with a moderate amount of clerical help, could be an ex officio member of all committees that need to carry on correspondence. He could also do a certain amount of research work for some of the committees. Until some such plan is put into effect the American Water Works Association is not likely to grow as rapidly as it should and, failing to adopt it, actual decline may come.

Construction of New Arch Section of Galveston Causeway

Centrifugal and Jet Pumps Mounted on Derrick Platforms—Permanently Lagged Steel Arch Centers—Old Causeway Walls Used for Cofferdam

OF MORE than a mile of earth fill which formed about two-thirds of the Galveston causeway prior to the storm of August, 1915, only the low concrete walls and the concrete sheet piling below them remained after that catastrophe. As communication with the mainland was then possible only by altogether inadequate ferries, two temporary trestles of wooden piles were built immediately—a highway structure several hundred feet distant to avoid interference in rebuilding the causeway, and a railway trestle along the old line of track which is still in use for the main portion of Galveston's railway traffic and by the Houston interurban electric line. Location of the highway trestle too far away to be of use for construction purposes, and constant service required of the railway trestle, combined with the fact that the bay was too shallow for water craft along the causeway, made necessary the use of the bottom of the bay along the structure for location of equipment and for transportation of material.



REBUILDING CONCRETE ARCH SECTION OF CAUSEWAY, USING OLD SHEET PILING TO FORM COFFERDAM

The old sheet piles and walls were well situated for forming a wide cofferdam to make this possible and allow the use of wide-gage derricks to handle the work on the new arches. Concrete plants at either end receive material either by railway or by barges passing through the deeper water at the southern end and a channel dredged from deep water to the northern end. Centrifugal pumps on the ground and on the platforms of the movable derricks, which also contained jet pumps, and two reciprocating pumps drawing water from several pumps, emptied the cofferdam. The portable steel arch centers were permanently lagged and moved ahead in halves by a derrick and a wide-gage car inside the cofferdam.

All the sand for the 80,000 cu.yd. of concrete and the 10,500 concrete piles came to the job in barges, while the stone came by rail, as did the 6,000,000 lb. of reinforcing steel. The 40,000 cu.yd. of excavation and the 53,000 cu.yd. of fill were handled by the derricks directly to and from the bottom of the bay. At the north end of the work, where the railway track facilities are better, a sand-unloading plant and a pile-concreting plant consisting of a mixer outfit and a form yard 300 ft. long, with storage for curing the piles, have been constructed in addition to the regular mixing plant. Three main construction tracks lead along the viaduct from this end. A narrow-gage track is used for moving the concrete piles and for general utility work. A 30-ft.-gage track is laid for the stiff-leg derricks. Outside of this is a narrow-gage track with switches, which is used for transportation of the concrete in four 1-cu.yd. bucket trains. For a part of the work a track on brackets along the railroad trestle carried the concrete for the foundations. At other places

REINFORCED CONCRETE PILE CASTING YARD AND PLANT FOR CONSTRUCTING GALVESTON CAUSEWAY

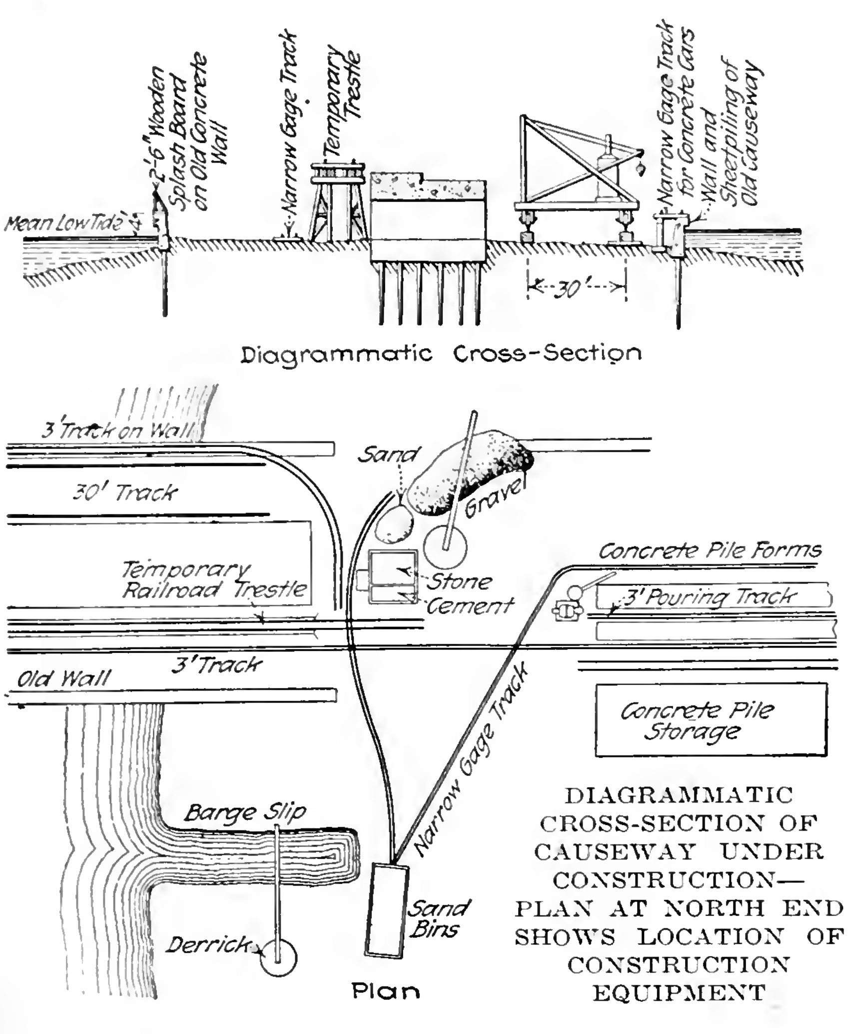
a narrow-gage track was placed on the near side of the derrick track, for convenience in moving material ahead.

The concrete sheetpiles and the walls surmounting them which retained the earth fill of the old causeway are far enough apart to allow working space between them and the new arches. In the construction of the new work these old walls are used as cofferdams and are found very tight. They are about 4 ft. above mean low tide, high enough to keep the water out except under strong winds. A 30-in. splash wall of boards has been built on the east wall to catch the ordinary spray of the waves. This is not water-tight, but throws the spray back and saves a great deal of pumping.

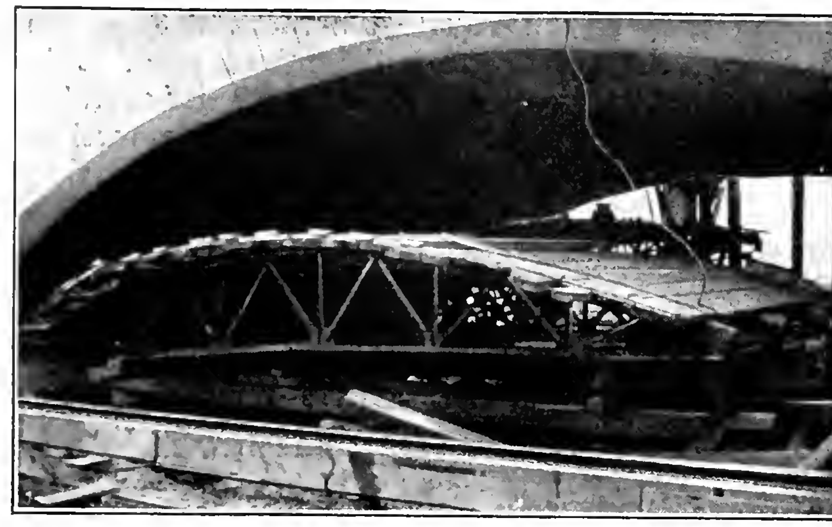
Most of the pumping is done by pumps mounted on the derricks. An 8- and a 10-in. centrifugal pump are used ahead of pier construction. A "line pump" system, composed of a locomotive-type boiler and two reciprocating pumps hitched in parallel, pumps from a pipe line with branches into the several sumps for 400 ft. each way from the power plant. By care in making the joints of this section line, it has been made to produce good results, and it is valuable in keeping the water down in holes behind pier construction and where other pumps are not available. Most of the derricks are equipped with 5- or 8-in. centrifugal pumps and with 3-in. duplex pumps for jetting. By moving several derricks into a desired section after a storm, it is possible to unwater it without much loss of time.

Both excavation and piledriving are done by the stiff-leg derricks—the former chiefly by clamshell. The piles are of concrete, varying from 19 to 35 ft. in length, according to the penetration which the soil will allow. They are driven with swinging leads hung from the ends of the derrick boom. A four-ton steam hammer of a medium quick-hitting type, with a special follower and double live-oak striking cushion, drives the piles with very little shattering of the concrete. When shattering occurs it is found always to be most severe at the top, and disappears completely in a foot or two.

Movable Steel Centers—Steel trusses with wooden lagging are used for the arch centers. The lagging is fastened to the trusses and moved with them. The trusses are of the three-hinged type, with a pin at the crown and jacks at either end. A tie-rod is provided about one-third of the way up to hold the trusses during erection. This is loosened before the concrete is poured. These trusses are removed after the concrete has set for 30 days. To strike them, the jacks are removed and the whole form is rolled part way out on rollers which replace the vertical jacks. Where the pins at the crown are within reach of the derrick they are removed, and the forms are lifted in halves and placed on a 30-ft.-gage truck for the removal to the next set-up.



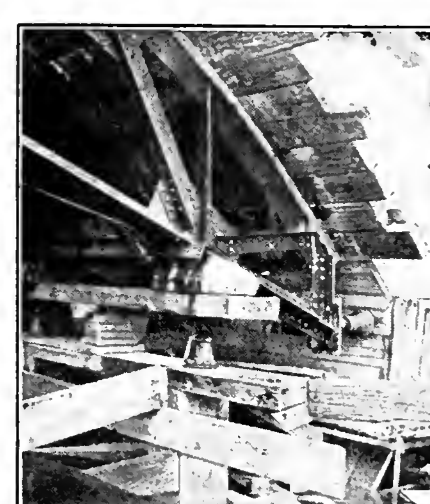
DIAGRAMMATIC CROSS-SECTION OF CAUSEWAY UNDER CONSTRUCTION—PLAN AT NORTH END SHOWS LOCATION OF CONSTRUCTION EQUIPMENT



STEEL ARCH FORM WITH LAGGING ATTACHED

During the latter part of the work narrow sections have been used, the railroad portion being poured first and then the highway, the lateral movement of the forms being accomplished without taking the trusses down. In setting up the forms the horizontal jacks are not placed until a day or two after the umbrella section over the pier has been poured.

The concrete plant at the north end of the work consists of a 1-yd. mixer with stationary measuring bins fed from wooden hoppers. These in turn are filled by a clamshell from car or storage piles of gravel and from piles of sand. This sand comes to the job in barges, and is unloaded by a derrick several hundred feet from the concrete plant into hoppers from which it is taken as required into side-dump cars. An endless cable operated by a reversible engine pulls the cars of sand up an incline, where they are dumped beside the mixer derrick. The mixer is arranged to dump into concrete buckets on flat-cars. One train is filled while the dinkey hauls one out and takes back the empties.

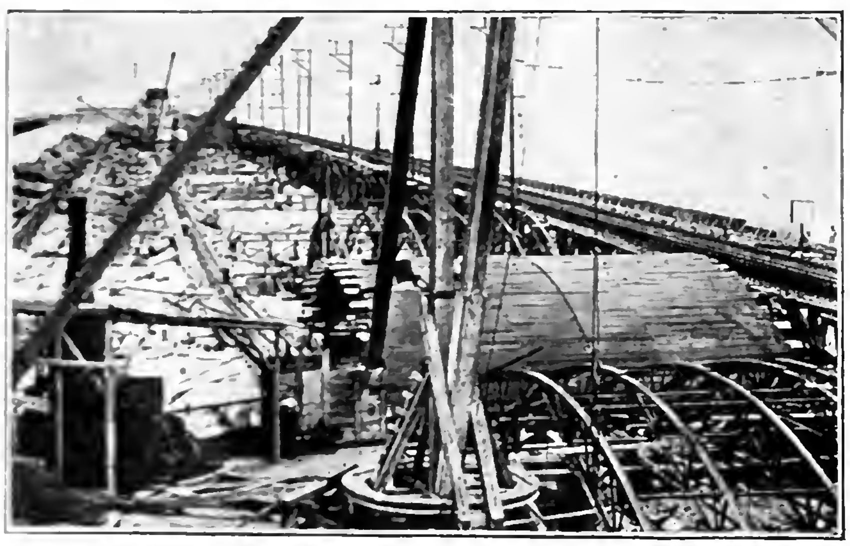


JACKING DETAILS AT ENDS

The reinforced-concrete piles used in the foundation work were made near the job in a special yard at the Virginia Point end. This concrete-pile plant had a mixer of its own and three tracks. The center one of these tracks was 3-ft.-gage and was used by the concrete car carrying the concrete to the forms. On either side of this, and between it and the standard-gage

tracks, were the forms for the piles. The standard-gage tracks were for the locomotive crane which handled the piles. The mixer plant consisted of an ordinary bin plant with a ¾-yd. mixer. It had a small tower high enough to dump into the concrete car. This concrete car was of peculiar construction, being nearly 20 ft. high and having a concrete hopper at the very top. The reason for locating the hopper so high was to allow the concrete to be chuted as far as possible from the car. From the concrete car the mixed concrete is chuted some 25 ft. to either side. This car was operated by an endless cable which was attached to a reversible engine.

The space for the concrete forms was a wooden platform on either side of the inner track. The bottom portions of the pile form were nailed permanently to this platform. The sides were of 2-in. material, as were the bottoms. They were movable. One day was required before the side forms were removed. Four days were required before the piles themselves were removed, and the total curing required 45 days.



PROGRESS IN ERECTION OF STEEL ARCH FORMS

As the length of the piles depended upon the depth of the sand stratum encountered at the site, an estimate was made from the borings at the foundation sites as to how many of each length would be required. About 75% of the piles were made from this estimate, with a few changes from time to time as foundations were put down.

As the second half of the railroad portion of the viaduct is yet to be built, any extra piles can be used there. After four days, the piles were picked up by a locomotive crane which handled them by means of two steel loops from the piles which were made a part of the reinforcing. After four to five days the piles were ready for driving.

With the exception of the handling of concrete materials, most of the crane work of the job was done by the wide-gage traveling derricks. Fourteen of these were single derricks with a platform 32 ft. square running on a track of 30-ft. gage. The boom was 65 ft. long.

A fifteenth derrick was double, being a little longer and having two booms, on opposite corners. Each derrick was equipped with one three-drum engine. Each platform or derrick outfit had a swinging engine, a 5- to 8-in. centrifugal pump, and a 3-in. duplex pump. Forge and work bench were also provided. These derricks were not equipped for rapid moving. They were moved by a line from the engine to a point at which it could be hitched ahead. This was entirely satisfactory, as they were often left in one place for a considerable time and very seldom required quick movement. For doing particularly heavy work, or when left a long time in one place, the frames for the derricks were blocked up to save the tracks and wheels.

WIDE-GAGE TRAVELING STIFF-LEG DERRICKS WERE MOVED BY LINE FROM ENGINE

H. F. Jonas is supervising engineer on the present construction work, which is being done on a cost-plus-fixed-sum basis by Larkin & Sangster, Inc., contractors of Buffalo, N. Y. A. A. Sangster is in active charge of the work for the contractors, with R. B. Norris as his general superintendent. Thomas A. Lowe was general superintendent at the beginning of the present work.

Water-Works Labor Prices in Boston District

Prices paid for labor in April, 1919, by 17 water-works in and near Boston, Mass., with information as to holiday and vacation allowances, are shown in the accompanying table, taken from a paper on the effect of the war on water-works, by Leonard Metcalf, consulting engineer, Boston. The paper was read before the meeting of the American Water Works Association in Buffalo, June 10, 1919.

LABOR PRICES PAID BY WATER-WORKS IN THE VICINITY OF BOSTON, APRIL, 1919

Place	Common Labor Per Day	Common Labor Per Hour Cents	Pipe Layers and Calkers Per Day	Pipe Layers and Calkers Per Hour, Cents	Hours per Week	Holidays	Vacation Two Weeks Paid

Progress and Problems in the Field of City Water-Supply

Abstracts of papers before the American Water Works Association at Buffalo—New reciprocating pumping engine, chlorination and typhoid reduction, effect of war on water-works finances, pitometer survey and house-to-house inspection at Buffalo, need for standardization of flanges for light cast-iron pipe

The "Unaflow" Pumping Engine

By D. A. Decrow

Chief Engineer, Worthington Pump & Machinery Company, Harrison, N. J.

THE "Unaflow" steam engine derives its name from the fact that the steam travels into and through the steam cylinder in one direction; it does not counterflow or return over its own path. It is not particularly new in principle, but its development as a practical and economical commercial machine is quite recent, and its adaptation to reciprocating pumping engine practice is new. After much experimental work by various inventors Prof. J. Stumpf overcame previous difficulties, and to him undoubtedly falls the honor of making the first practical and commercially successful application of its principles to modern steam-engine practice.

The general principle of the "Unaflow" reciprocating steam engine is that of utilizing the heat energy of the steam in the cylinder during the period of its admission, expansion and flow in one direction, the expanded steam being released or exhausted through ports or openings uncovered by the travel of the cylinder piston at that period of its stroke most remote from the point of admission.

In the accompanying sketch of a typical "Unaflow" engine the piston is at one end of the stroke with the exhaust ports uncovered. The arrow indicates the path of the steam through the cylinder. The indicator diagram shows that steam is admitted into the cylinder for only a very minor portion of the stroke and is then cut off, the work performed during the remainder of the stroke being due to the expansion of the steam after the inlet valve closes. The exhaust opens when the piston, which is much longer than the ordinary steam-engine piston, travels past and uncovers the exhaust ports midway between the two ends of the cylinder.

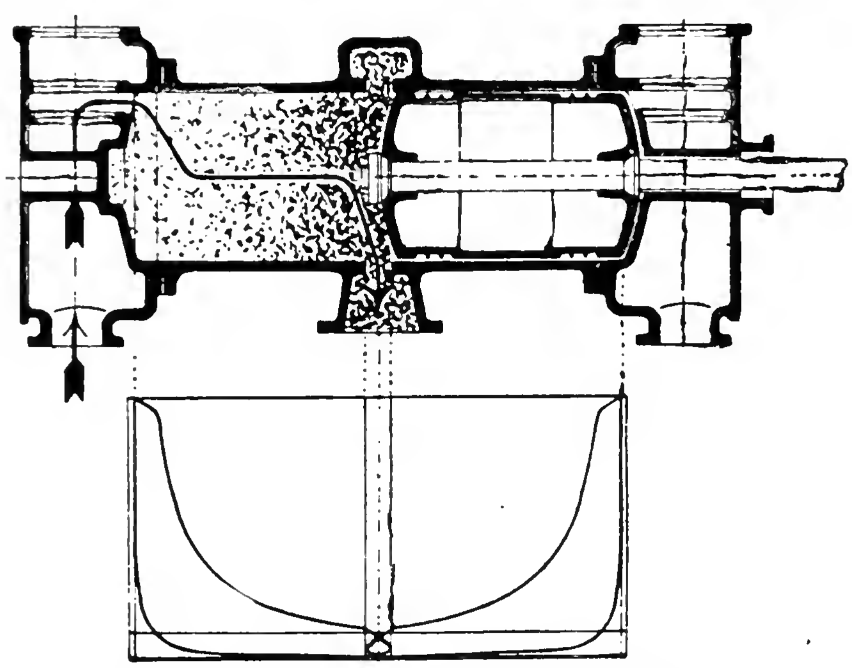
Beginning with the steam in the cylinder, there is practically no change of temperature until the point of cut-off. After cut-off, expansion takes place with a consequent drop in temperature and at this time condensation begins, due to the changing of heat into work. As the cylinder head is jacketed with high steam, no condensation takes place on the walls of the head, but the condensation is on the wall of the piston, which is comparatively cool and adjacent thereto, so that at the end of the stroke, when the piston uncovers the exhaust ports, the moisture of condensation is mostly at the exhaust end of the cylinder, and as the steam expanding away from the cylinder head rushes out through the exhaust port, it carries the moisture with it.

At this time there is a sudden drop of temperature in the cylinder due to the sudden drop of pressure, but as the inlet end of the cylinder is dry it does not lose its temperature. The exhaust port is covered by the piston on the return stroke, trapping in the cylinder comparatively dry steam partially superheated. As the walls of the cylinders have retained their heat, the heat of compression is not absorbed either by moisture or by cold walls, as in the case of a counterflow engine, and the steam remaining in the clearance is heated by compression to a temperature above the temperature of the initial steam. When the valve is opened to start the next stroke, the live steam rushing in goes into a clearance space in which the steam entrapped is hotter than the entering steam, hence there is no initial condensation. Owing to the complete removal of all the mixture of each stroke, the well known heat losses that are caused by the presence of water in the counterflow engines are avoided.

Eliminating initial condensation permits an economically high ratio of expansion in one cylinder. For normal working conditions about 16 expansions have been found to give best results.

It is also evident that, with the use of exhaust ports in the cylinder instead of the usual exhaust valves, leakage losses at the exhaust valves and of all of the added clearance space and surfaces, which losses necessarily follow from the use of a special exhaust valve, are eliminated. It has been found practical to reduce the clearance space in condensing engines to 3% of the swept volume of the piston.

Some of our manufacturers of "Unaflow" steam power engines have guaranteed as low as 10 lb. of steam per

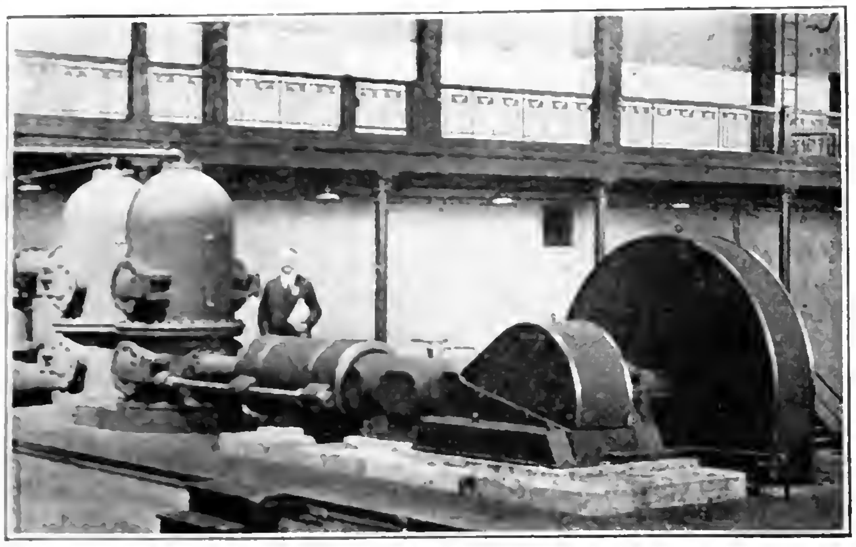


TYPICAL "UNAFLOW" STEAM CYLINDER AND INDICATOR CARD

indicated horsepower per hour, and some of the tests of European built engines have shown well under nine pounds.

Taking into consideration its simplicity—for with a single cylinder substantially the same economy is obtained as with the best types of compound- or triple-expansion steam engines—the "Unaflow" engine marks a distinct step in advance of the other types of reciprocating engines. These advantageous features have attracted attention to its desirability as a motive power for reciprocating pumping engines.

To develop a pump that could be combined with and utilize the advantageous features of the "Unaflow" engine requires that due consideration be given to proper



"UNAFLOW" TEST PUMPING ENGINE AT BUFFALO

channels for passing the desired amount of water to and through the pump with the least practicable amount of deflection and disturbance of the flow. This can best be attained by incorporating the "Unaflow" principle in so far as it will apply to a pump. The pump should be provided with passages ample and direct, so there will be no reversal of flow, with plungers properly proportioned and formed to cause a minimum disturbance, with suitable suction and discharge air chambers properly located with pump valves that will deflect the direction of flow as little as possible, that will operate quickly and quietly at all pressures and economic speeds of the engine, and, furthermore, that will be durable and lasting in operation.

One of our pumping engine manufacturers has designed, constructed, erected and will operate in the Porter Ave. water-works pumping station of the City of Buffalo, especially for the inspection and information of the members of this convention, a complete "Unaflow" high-duty condensing pumping engine of about 3,000,000-gal. daily capacity. Tests of this machine will be made later and the results published. It is anticipated that the tests will show a duty of 180,000,000 ft.-lb. of steam.

This engine is of the horizontal extended type (so-called), having one steam cylinder and one double-acting plunger pump. Its normal working water pressure is 100 lb. per square inch; the suction left is approximately 15 lb. plus the friction in about 60 ft. of suction pipe. The normal steam pressure at the Porter Ave. station is 235 lb. per square inch with 100° F. superheat.

Advance in Chlorination and Its Effect on Typhoid Fever

By John Kienle
Sanitary Engineer, Electro-Bleaching Gas Company, New York City

Chlorination of public water-supplies has been the most noteworthy single contribution to the art of water purification in recent years. The effect of this method of water treatment in reducing the typhoid mortality of the country at large is attested not only by the statistics but by the increasing demand of public health authorities for this method of protection.

Chlorination of water by the hypochlorite of lime method was first carried out successfully in the United States by George Johnson at the Union Stock Yards at Chicago in 1907, and almost immediately followed by the treatment of the Jersey City supply at Boonton. By the end of 1911 approximately 500 water plants had been equipped with hypochlorite installation. In 1912 the use of liquid chlorine was announced at the Minneapolis convention of this association. Although the increase in the use of hypochlorite was quite rapid following its appearance at Boonton, the rate of growth of the liquid-chlorine process was even more remarkable. From only one water plant (Niagara Falls), equipped at the end of 1912, the number at the end of 1918 had jumped to approximately 2500.

In 1907, the United States Census Bureau tells us, the typhoid-fever death rate in the registration area, with a population of 41,758,000, was 30.3 per 100,000, and the estimated number of deaths within the year for the entire country was approximately 30,000. There were then no chlorinated water-supplies. In 1917, according to the United States Public Health Service, the rate had dropped to 12.3 per 100,000, with the estimated number of deaths stated at 13,000, and in this year there were at least 2000 public water-supplies that were chlorinated. Thus 17,000 lives were saved from death by typhoid in one year. This is a saving of over $125,000,000 annually.

It has been aptly stated that the chlorination of public water-supplies is the cheapest municipal insurance that can be obtained, the average annual premium amounting to not more than 40c. per 1,000,000 gal. of water treated, or, for a municipality of 5000 or less, an annual expense of $150 per annum ($36.50 operating, and $120,000 depreciation at the rate of 20%) or a cost of 3c. per capita, based on the same figure of 5000 population.

Effect of the War Upon Water-Works Revenues and Expenses

By Leonard Metcalf
Consulting Engineer, Boston, Mass.

The situation with regard to the water-works of the United States is probably fairly shown by the accompanying comparative records of about 50 plants with aggregate annual revenue of about $35,000,000 and supplying a total population of upwards of 9,000,000 persons, or nearly 9% of the entire population of the United States. The data for 1914-17 were presented to the association a year ago by its committee on war burdens of water-works. The 1918 figures have been collected and added by the writer. These records indicate that:

1. The annual revenues with such increase in rate schedules as were granted by the regulatory authorities

TABLE I. COMPARATIVE WATER-WORKS REVENUE AND EXPENSE, 1914-1918, IN PERCENTAGES OF 1915

Group	1914	1915	1916	1917	1918
Percentage Gross Annual Revenue					
Eastern	95.7	100	110.1	112.8	120.6

Southern	97.7	100	107.5	120.3	126.3
Western	101.7	100	107.3	109.5	117.5
Average	98.3	100	108.5	113.5	122.7
Percentage Operating Expenses, Including Taxes					
Eastern	99.7	100	121.9	141.1	149.7
Central	100.9	100	109.3	137.3	162.3
Southern	97.0	100	109.7	134.6	165.9
Western	98.6	100	109.9	117.4	128.0
Average	99.0	100	112.7	132.6	151.5
Net Revenue Applicable to Depreciation, Interest, Dividends and Surplus					
Eastern	90.9	100	103.0	90.4	105.8
Central	97.3	100	110.0	98.5	106.5
Southern	97.9	100	96.3	104.0	89.1
Western	103.6	100	104.3	105.3	114.4
Average	97.4	100	103.4	99.6	104.0

and put into effect by the plants, have increased at an average rate of approximately 7% per annum, slightly less than a normal amount.

2. The operating expenses, including taxes where taxes are paid, and excluding them where none is paid, have increased over the year 1915 abnormally, by 13% in the year 1916, 33% in the year 1917 and 52% in the year 1918.

3. The net (operating) revenues applicable to depreciation, interest, dividends and surplus, have substantially stood still since the year 1915.

The average increase in population in this country has been at the rate of approximately 1.9%, compounded annually, and of the cities supplied by these 50 typical water-works, about 3.1 per cent.

The net revenue of water-works usually increases at the rate of from 4% to 5%, compounded annually. Yet the total increase in the three-year period from 1915 to 1918 is but 4%, against a normal amount of from 12% to 15%, in spite of increases granted by the commissions.

The records gathered indicate further that the increases in rates granted to water-works by the commissions seem to have amounted on the average to about 10%, serving thus to decrease the loss in net revenue in the year 1918, from 20%, more or less, to 10% or thereabouts. If this inference is sound, the loss in operation was divided equally between the works and their consumers.

It is clear, however, that the burden of increased operating expenses, plus the interest upon the new investment put into these properties during the war period, has been *borne by their owners*, in larger measure than by the public, except in the case of publicly owned works.

Unskilled Labor Costs, in cents per hour (see Table II) did not generally feel the influence of the war until the middle of the year 1916. As compared with pre-war conditions, reflected by the prices prevailing in 1915, they increased one-eighth in 1916, one-fourth in 1917, and nearly three-fourths in 1918. The increase was felt most markedly in the South and upon the Eastern seaboard, being nearly doubled in the first, and increased by three-fourths in the latter district. The wages paid upon the Pacific coast before the war, which were much higher, have advanced relatively less than elsewhere, so that at the present time the Eastern and Western unskilled labor prices are about the same. Thus the average rate in the Western group increased from 27c. per hour in 1915 to 42c. in 1918; while the Southern rate increased from 18c. to 34c.; the Central group from 22c. to 37c.; and the Eastern group from 23c. to 40 cents.

In spite of the general business uncertainty and resulting depression, wages paid to unskilled labor, by water-works in the vicinity of Boston, have advanced from approximately 41c. per hour, under date of Sept. 14, 1918, to approximately 46c. per hour in April, 1919, without allowance for the effect of vacations and holidays under pay, granted by some works. Present (June, 1919) conditions give little if any indication of reduction in prices this year, or hope for any marked reduction in the future.

Cast-Iron Pipe Prices (Table II) which had about trebled at their maximum point, have now receded to about twice pre-war figures. *Valves, Hydrants and Pumps*, which had more than doubled in price, are now to be had at an advance of something over seven-eighths of pre-war prices. *Coal and Fuel Oil Prices*, which more than doubled, have receded somewhat. *Chemicals* used in the purification of water, which, by reason of outstanding contracts showed an average advance of but one-third, though the market price had increased approximately three-fourths, have decreased so that the present excess cost is about one-half over pre-war prices.

Future Prices—Engineers prefer the rôle of interpreter of facts to that of prophet. It is desirable, however, to note here probable future price tendencies. First, with respect to unskilled labor, no marked change is to be looked for; and with respect to the rates paid to water-works employees, it is believed that the prices now paid are likely to continue in most cases, and to increase rather than to decrease in the remaining cases.

TABLE II. INCREASE IN COST OF LABOR AND MATERIALS TO WATER-WORKS IN THE UNITED STATES, AS REPORTED TO THE EXECUTIVE COMMITTEE OF THE AMERICAN WATER WORKS ASSOCIATION, MAY, 1918, AND REVISED, APRIL, 1919, BY LEONARD METCALF

		Prices per Unit				Per Cent. Increase Over 1915			Year 1918

* Note. It was generally reported that there has been also a marked decrease in efficiency of labor since 1914, variously estimated at between 20% and 50%; and that the increase in wages paid to labor by water-works had not kept pace with contract prices, owing probably to the advantage of continuity of service.

† See *Journal of Industrial and Engineering Chemistry*. Note that 1915 price was an advance of 34% over the 1914 average price before the advances listed went into effect.

Unless Bolshevism runs its course in this country, or industrial depression should follow the war—neither of which seems likely—an active demand for labor is to be looked for in the near future. It is to be remembered that, despite the war, the population of this country has been increasing at a rapid rate. Immigration has been at a standstill, and in the light of home demand for labor abroad, does not seem likely to be active for some time to come. Many employers, contractors and labor leaders believe that in the not distant future this country is sure to feel the competition for available labor and that this will stimulate yet higher wage scales.

NECESSARY IMPROVEMENTS SHOULD GO FORWARD

Second, with respect to materials of construction, there is greater hope for relief. Nevertheless, no substantial reduction in the price of cast-iron pipe, valves and hydrants seems likely for the present year, and but a gradual reduction is to be looked for in the future. In spite of the increased facilities for production, the labor, transportation and money conditions involved seem likely to make themselves adversely felt for some time, and the losses resulting from the war seem likely to be permanent.

Third, the materials of operation—coal, fuel oil, and chemicals—do not appear likely to decline markedly in cost, and such tendency toward decrease as there may be will probably cause the making of short-time, rather than long-time, contracts for such supplies.

The Future—The conclusion to be drawn from the present physical and financial condition of water-works in the United States seems clearly to be that *necessary improvements should go forward as rapidly as possible.* It is desirable to restore public confidence and further the Government's wise wish to give employment to idle labor. More important yet, *improvements are seriously needed to restore our normal high standard of water service, to safeguard adequately the public health.*

While city officials and water-works men are hesitating, the large manufacturing interests, dominated by shrewd, farsighted business men, are going ahead with their construction work, with their plant extensions and housing projects, confident that postponement will at best offset increased cost in small measure; will probably involve loss in service or profit far exceeding any saving in construction cost; and at worst will involve yet higher costs, coupled with increasing difficulties due to a vanishing labor surplus.

The public is far more vitally interested in thoroughly good and adequate present service than in any probable saving to be effected by delaying construction to a later date, in anticipation of further, more or less problematical, decline in costs.

Reduction of Water Consumption By Pitometer and Inspection

BY GEORGE C. ANDREWS
Water Commissioner, Buffalo, N. Y.

IN 1897 the Buffalo common council decided it would be more advantageous to its citizens to install additional pumps and give practically an unlimited supply of water than to control consumption by means of meters. It would be interesting to speculate on what that decision has cost the citizens of Buffalo in the past 22 years. Suffice it to say that in 1903 the Bureau of Water had a bonded debt of $3,699,382 while it was $12,141,524 in 1917. In 1903 there was one pumping station, with a daily capacity of 183,000,000 gal. In 1917 there were two pumping stations, with a combined daily capacity of 330,000,000 gal. Coincident with the increased pumping capacity large distributing mains were laid. During this period the per capita consumption ranged between 302 and 339 gal. per day. Of this practically 100 gal. was for industrial use.

In 1916 a commission of five men was selected to govern the city. One of its early efforts was an investigation of means to reduce the water consumption by the city.

As all water used must be pumped from Lake Erie against a head of 140 to 204 ft., a reduction in pumpage would make an immense saving in coal for fuel. In the spring of 1917 it was decided to start a pitometer survey. This was supplemented by house-to-house inspection. Metering was considered, but was rejected on various grounds, some of which were the following: Popular local predjudice against metering; length of time to meter the city completely, there being over 76,000 unmetered and active services, while the pitometer method promised early results; extensive changes in plumbing required should meters be installed in many of the poorer types of dwellings; heavy initial investment required for meters.

To make the survey, an engineer in charge and four assistants were employed. Three trucks with gangs of four were constantly engaged, and one clerk was assigned to this work to keep the records. Twelve of the regular city inspectors made the house-to-house inspections. Later, as more of the city was covered, 20 temporary inspectors were engaged. One of the assistant engineers made the district measurements, and two were constantly engaged on subdivision. An assistant engineer tested the meters and fire lines. During the winter months two men worked in the office.

BUREAU INTENDS TO CONTINUE PITOMETER WORK

As work was completed in each division, a permanent map was filed in the office, showing gaging points for instrument and valves on boundary points. On this map are recorded the date of the first measurement, 24-hour consumption and minimum night rate, and same record of second measurement. It is the intent of the bureau of water to continue the pitometer work as a special department. Regular measurements will be taken at varied intervals, and these maps will facilitate the work greatly. All inspectors' reports are filed by streets and can be referred to instantly. As soon as a section was completed, a full report on it was submitted by the engineer-in-charge. This report gave a general summary of the work, with certain specific recommendations to meet the conditions for the sections. These reports are filed so as to be available for future reference.

Our first section was surveyed in 1917, and this year remeasurements have been taken. These show that there is a more or less gradual return of the waste first eliminated, depending wholly on the character of dwellings. In all sections the consumption was less than it was two years ago, at the time of the first measurement. I estimate that effects of the result of the survey will be from one to three years as far as house waste is concerned. All underground leaks stopped are a permanent saving.

Nine-tenths of the city has now been covered by the survey, with the following results:

	House waste stopped, 18,000,000 gal. (estimated)
	Underground waste stopped, 12,000,000 gal., actual measurement
33,278	leaky fixtures reported and repaired
1860	leaky services reported and repaired
52	unfinished supplies found wasting 3,587,000 gal. per day
	Broken mains and leaky joints wasting 4,376,000 gal. per day found and repaired

The pumpage has been reduced, except in times of extremely hot or cold weather, to less than 125,000,000 gal. per day, as compared with over 160,000,000 gal. per day in 1917. Figuring the cost of pumping at $6.24 per 1,000,000 gal., the average cost for the past three years, the annual saving is $68,328. Against this is the estimated charge of $25,000 per year to maintain the pitometer division of the bureau. To date the survey has cost $96,931, much of which represents permanent investment in equipment and records, or for professional services. Including the pay of temporary inspectors, who will be employed each spring, it is estimated that the annual cost of continuing the work will be $25,000 per year.

From the survey made and the results obtained, it is evident that to a certain extent the house waste can be greatly reduced by house inspection controlled by pitometer measurements. When these measures are used in conjunction with selective metering, the most flagrant house waste can be eliminated and the consumption reduced nearly to that obtained by universal metering, and done at less expense. The pumpage can be reduced at least 20,000,000 gal. by the installation of 10,000 meters on house services where tremendous waste has been found by the survey. The installation of these meters is now proposed. A further reduction is not deemed advisable until a filtration plant is built.

A comparison between the cost of universal metering and the elimination and control of waste by the pitometer and selective metering is, briefly, as follows:

Control by pitometer and selective metering:	
Annual cost of inspection	$25,000
Installation of 10,000 meters, investment in meters, $100,000	
Annual charge on meters, interest at 4½%	4,500
Depreciation	4,000
Cost of reading and maintenance	6,000
Total annual cost	$39,500
Universal metering:	
Installation of 75,000 meters, investment in meters, $750,000	
Annual charges on meters, interest at 4½%	33,750
Depreciation, 4%	30,000
Cost of reading and maintenance	45,000
Total cost	$108,750
Annual saving in favor of pitometer control	$69,250

It is true that universal metering would reduce the consumption considerably more than the other method, but even if the reduction amounted to 20,000,000 gal. per day the saving in operation costs would not equal $69,250 per year.

Need for Standardization of Flanges for Light Cast-Iron Pipe

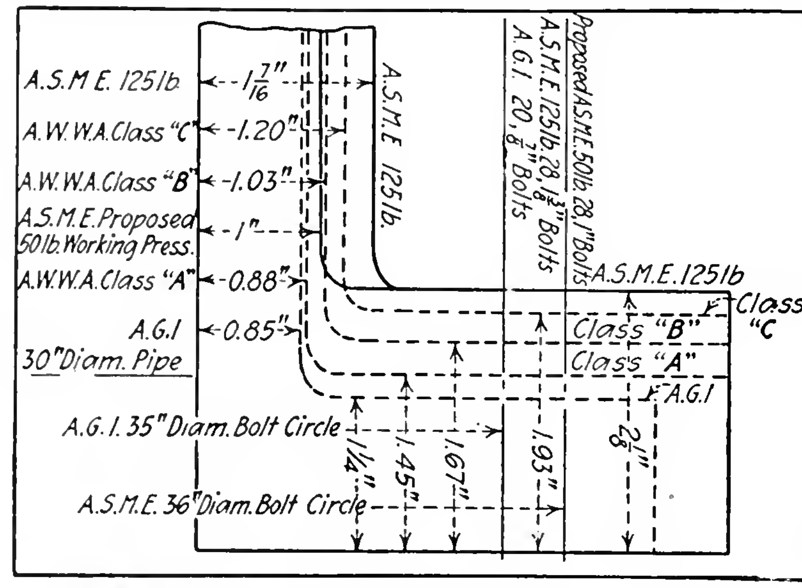
By John Knickerbocker
President of the Eddy Valve Company, Waterford, N. Y.

The question of flanges for light cast-iron pipe has come up for discussion at various times, but up to now no final action has been taken. Early standardization is desirable.

To bring this subject to the attention of this association and all others interested, an illustration is presented showing the thicknesses of pipe, and thicknesses of flanges for American Water Works Association Class A, B and C pipe, the flanges for these pipes being calculated by the formula, thickness of flanges equals 1½ times the thickness of pipe, plus ⅛ in.; the thicknesses of pipe of the American Gas Institute, and the thicknesses of flanges and bolt circles adopted by them; the A. S. M. E. proposed standard for 50-lb. working pressure, and the American Standard [also A. S. M. E.] for 125-lb. steam working pressure.

It is a serious question whether the standard flange suggested by the American Society of Mechanical Engineers for pipe for 50-lb. working pressure is not too heavy and would cause casting strains and shrinkage where the flange meets the pipe. Or take the 30-in. pipe, Class A, American Water Works Association pipe, which is 0.88 in. thick. Would it be good foundry practice to cast a flange measuring 2⅛ in. thick to this thin pipe, and if the pipe were increased to 1 in. thick, the thickness proposed by the American Society of Mechanical Engineers for 50-lb. working pressure, would not the flanges 2⅛ in. thick be too heavy for the pipe?

The American Gas Institute pipe thickness for 30-in. pipe is 0.85 in. Taking the inside diameter of the



COMPARATIVE DATA OF FLANGES FOR LIGHT CAST-IRON PIPE

The proposed A. S. M. E. 50-pound working pressure and the American Standard have the same diameter bolt circle

flange at 31.7 in. (the outside diameter of the pipe), the weight of the American Gas Institute flange is 102.4 lb. and the flange proposed by the American Society of Mechanical Engineers for light pipe is 215.5 lb., which is over twice as much as the American Gas Institute 30-in. flange. If the American Gas Institute flange is heavy enough for Class A pipe, then for each flange 113.1 lb. would be wasted if the American Standard flange were used; besides the poor casting that might result from casting so heavy a flange on a light pipe.

If a flange 1.67 in. thick were used on a 30-in. Class B pipe, taking the outside diameter of the pipe as the inside diameter of the flange, it would weigh 169.38 lb. The American standard flange on this pipe would weigh 215.5 lb., showing a saving of 46.12 pounds per flange.

If it were possible to use the American Gas Institute flange for the Class A pipe, and a flange of the diameter of the American Standard, but between the thickness shown for the flanges for Class A and Class B pipe, as calculated by the formula already given, it might be a good solution of the question.

Would it not be well for the committee of this association which has this matter in charge to endeavor to take it up with like committees from the New England Water Works Association, the American Society

of Mechanical Engineers, the American Gas Institute, the Cast Iron Pipe Manufacturers, the Committee of Manufacturers on Standardization of Fittings and Valves, and such other organizations as might wish to be represented?

Progress by Engineering Council's Compensation Committee

Seriousness of Situation Considered and Principles for Classification and Salary Schedule Are Proposed

REPORTING at the recent regular meeting of Engineering Council, the committee on classification and compensation of engineers presented the following analysis of the situation and suggested the lines of its future action. Reports from separate sections of the committee are also briefly abstracted herewith:

In attempting to formulate standard rates of compensation for professional engineers, the first task is to find what rates are actually in force, especially in those fields where attempts at standardization have been made. The second task is to inquire what adjustment should be made to correspond to the great change which has taken place in the cost of living, or, in other words, in the value of the dollar. How great this change has been during the past 20 years is realized by few. Fortunately, an accurate determination is available in the statistical records of average prices which for many years have been gathered and published by leading commercial organizations.

A record of average prices of the necessaries of life kept by R. G. Dun & Co. shows that prices have increased continuously for 22 years. A certain quantity of staple necessaries could have been purchased July 1, 1897, for $72.45. By Jan. 1, 1905, the same quantity cost $100.32. On Jan. 1, 1914, before the outbreak of the war, the cost had risen to $124.53; May 1, 1917, to $208.43, and Oct. 1, 1918, to the maximum of $233.23.

Salaried Worker Has Had No Such Increase as Wage Worker

This enormous increase in prices of the necessaries of life has been accompanied by an increase in wages, especially among workers organized in unions which had the power to compel attention to their demands. In the unskilled labor market the relations of supply and demand raised wages during the war to points in some cases exceeding the increase in the cost of living. No such increase has taken place in the compensation of salaried workers in the professions. It has been assumed that these workers, living in a different social environment, had a margin of compensation sufficient to enable them to meet the increased cost of living. This assumption is not justified by the facts. Where salaries have been increased during the past three years, there are few cases in which the increase has been at all commensurate with the increase in prices of the necessaries of life, which the salaried worker, like the wage worker, has to purchase. That this is a correct statement is amply proved by many direct comparisons which have been made of the wages of the workers in various skilled trades and the salaries of the rank and file of technical and professional workers.

There is little doubt that an unprejudiced investigation would show that a large proportion of the salaried workers in professional occupations during the past three years have been unable to pay their living expenses from their earnings and have been obliged to rely on income from property owned or to use up savings of other years in order to maintain themselves.

A serious question is whether the present scale of prices is here to stay. There has been a general belief that with the coming of peace and the resumption of productive industries a heavy fall would occur. It has been assumed that the salaried worker would have to wait for this so that he could again live within his income. It now appears, however, to be the opinion of many financiers and economists that the present high prices of necessaries are likely to continue for a long time, probably for several years. The salary of $2000 a year which a man received from 1902 to 1905 will now buy less than $1000 worth of necessaries. This has been the case for two years. If this is to continue for two, three or four years to come, then surely the salaried worker, in a professional or any other occupation, has an equitable claim to have his compensation brought back in purchasing power to where it was fifteen years ago.

There is another aspect of the compensation of the professional worker which has been frequently misunderstood, but which, with present knowledge, ought no longer to deceive. The pay of professional engineers has for many years been influenced by the idea that a young man in the earlier years of his work should expect moderate compensation because of the future to which he might look forward. In Great Britain this idea found expression for many years in the custom of the young engineer paying a premium during a number of years' service in order to learn the business. There was justification for this idea during the period when the development of engineering was so rapid that a large proportion of the men who were turned out from the few engineering schools or the engineering workshops were able eventually to rise to positions of large responsibility and importance, commanding high salaries.

That condition has been altered. Of the men who begin technical engineering work today, only a very few selected ones can rise to positions of responsibility commandnig high salaries. The rank and file must inevitably be ten times as numerous as the captains and lieutenants, and a hundred times as many as the majors and generals.

The man of exceptional ability, indeed, may find it worth his while to work for low compensation because of the future awaiting him. But to hold up to the rank and file of technical workers the idea that they can afford to work for insufficient salaries for the sake of some future high position, which they have not one chance in twenty or fifty of attaining, is a gross deception.

In Public Interest That Engineers Be Well Paid

The committee believes, therefore, that in adopting standards for the compensation of workers in all technical fields due consideration must be given to the great increase in the cost of living which has taken place. The dollar of salary must be considered with regard to what it will purchase today and is likely to purchase next year, and not with regard to the value of the dollar ten or fifteen years ago.

This increase in compensation is necessary not merely as a matter of justice to the engineer, but in order that engineering work may be maintained on the plane that it must be to secure economical and efficient work. Not only the leaders but the rank and file of technical workers often have it in their power largely to affect the cost of the work in their charge by the quality of the effort they exert.

There is no economy in paying such men at rates inadequate for their support, for this leaves their minds burdened with anxieties, when they should be free to give their best efforts to the work in hand. Moreover, such a rate automatically tends to drive the abler men into other occupations and to leave in charge of the work only those of less ability, who are unable to make a change.

The municipal and state section of the committee, Arthur S. Tuttle, chairman, reported that it was formulating a standard classification of positions and duties, and a schedule of titles and qualifications has been prepared to be incorporated in a questionnaire for circulation among engineers of all states and the more important cities.

The Federal Government section, John C. Hoyt, chairman, reported that a survey of Government activities shows 28 offices that employ Government engineers. A letter was sent to each member of the Cabinet requesting a list of engineering bureaus in his depart-

ment, and favorable responses were received from all except the Secretary of War.

The railroad section, Francis Lee Stuart, chairman, reported that a questionnaire had been prepared to be sent to the chief engineers of the railroads under Federal control, but after conference with Director General Hines it was decided to send it to members of the founder societies who are connected with railroads. A letter outlining the work of the committee and suggesting a simple general classification into eight groups accompanied the questionnaire. These eight groups of engineers are as follows:

(1) Chief administrative officer having full charge of organization, including determination of policy; (2) head of major subdivision in responsible charge of large unit; (3) head of intermediate subdivision in responsible charge; (4) head of minor subdivision; (5) on general duty under direction but requiring special education and special training and the use of initiative and originality; (6) on subordinate duty requiring special education or training but not requiring special originality; (7) on subordinate duty not requiring special education, training or originality; (8) on special duty of responsible character requiring particular qualifications and initiative.

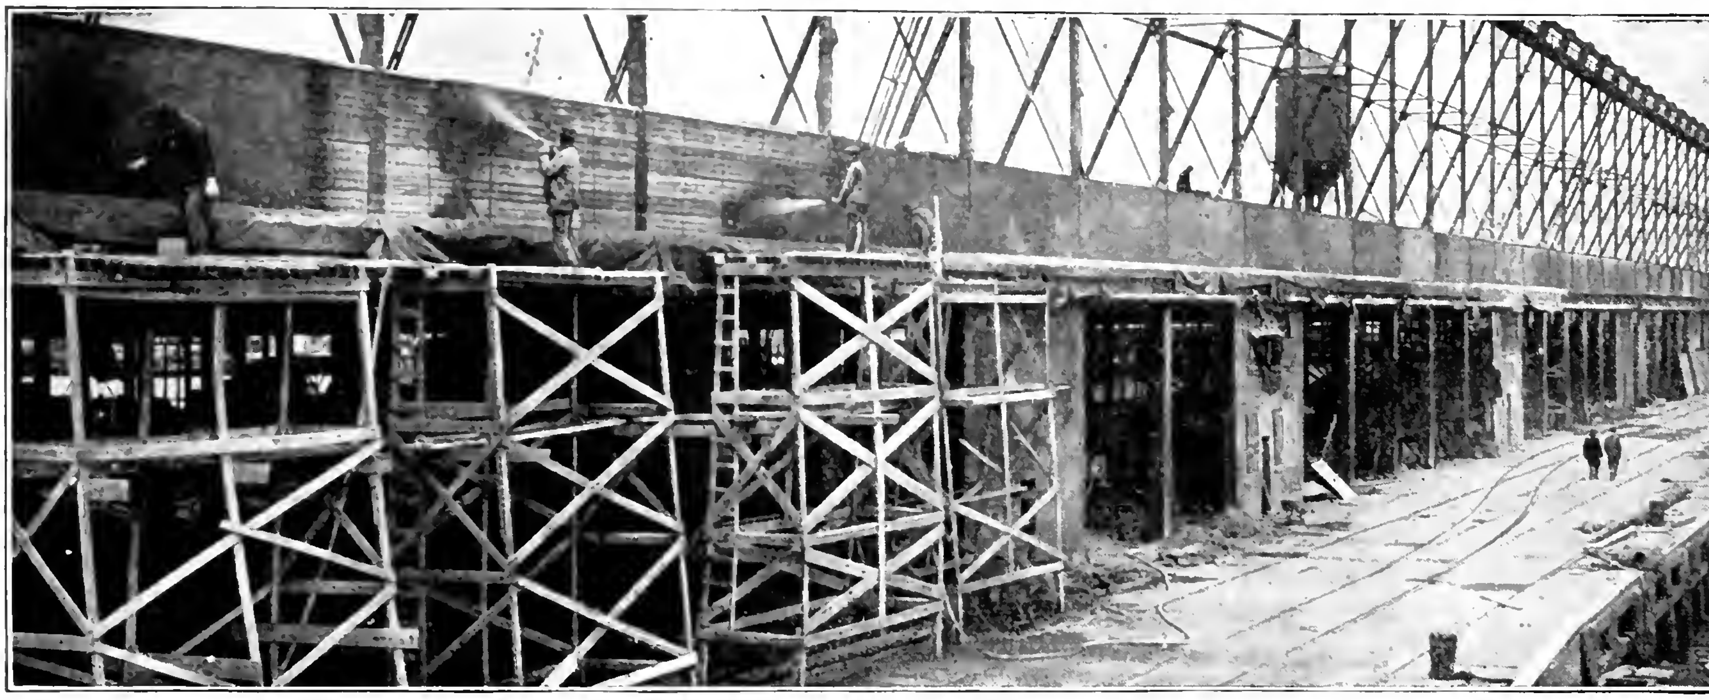
Michigan Is Active in Water Purification

There are now in Michigan 22 chlorination plants, besides 10 filter plants using chlorine, according to a statement by Edward C. Rich, state sanitary engineer. With few exceptions, each installation has a laboratory where daily analyses of the raw and the treated water are made and from which monthly reports are sent to the State Board of Health. Some trouble has been experienced in getting the appointment of competent analysts to take charge of the smaller plants, but the reports from the laboratories are mainly satisfactory. The results in protection of public health are considered to warrant fully the expense of equipping and maintaining these plants and laboratories. The methods recommended by the American Public Health Association are used in the laboratories, and the United States Treasury Department standards for drinking water on interstate carriers are used in interpreting results.

Cement Guns Built Walls and Roof of Army Warehouses

During the War Steel and Timber Framing Covered With Wire Was Coated With Gunite Shot in Place—Materials Transportation Reduced

CONCRETE walls and wide roofs were placed with the cement gun on timber and steel frame warehouses and pier sheds on the United States Army Base at Norfolk, Va., during the war, as was reported in an article in *Engineering News-Record* of Mar. 7, 1918, p. 462, although at that time the location of the port was not announced. Land being cheap as compared with that for Army bases in large cities, the warehouse facilities there are provided in the form of large one-story buildings, with a view to securing convenience and rapidity in making up cargoes. On the site of 640 acres there are eight warehouses, serving two piers, the former having nearly 2,500,000 sq. ft. of floor area and the latter having sufficient frontage for 12 large ocean steamers.



CONCRETE FOR SIDE WALLS AND PIER IS SHOT INTO PLACE—THE STEEL FRAMING ABOVE THE WALL IS FOR CARGO-HANDLING EQUIPMENT

Transportation difficulties at the time of construction made it imperative to use local material as far as possible. Sand being plentiful, it was decided to make the walls of 2-in. concrete, with the 1 : 3½ mixture as placed by the cement-gun process. This was employed for six warehouses, while one has brick and the other has tile walls, the latter being weatherproofed with a stucco coat applied by the cement gun. These buildings are 160 ft. wide and 1400 and 1680 ft. long, with transverse firewalls of brick 140 ft. apart.

Timber framing for the warehouses includes posts spaced 10 ft. on centers, carrying girts and caps and roof joists, the posts having 3-in. plank sheathing with tar and gravel roof. Wire netting of triangular mesh was secured to the posts and girts by wire nails and by wire chairs which kept the netting about ½ in. away from the wood, as described in *Engineering News-Record* of Apr. 25, 1918, p. 819. On the inside of the building are placed wood-form panels about ½ in. behind the wire, and the gunite is shot in place from the outside to build up a wall about 2 in. thick. After 24 hours the panels may be removed and set up for the next section of the work.

ARMY WAREHOUSES HAVE TIMBER FRAME WITH GUNITE SIDE WALLS AND BRICK FIRE WALLS

Each of the 1280-ft. piers has a steel frame shed in three bays, the middle bay being the higher and forming a monitor. On the outside is a wall extending down about 11 ft. from the roof to the continuous line of doorways, except that at the offices and toilet rooms this wall extends to the bottom of the building. In the side bays every eighth roof truss is cased in concrete to form a firestop. Between the upper ends of the interior columns are longitudinal concrete curtain walls or screens 12 ft. deep, so that smoke from locomotives in the middle bay will not escape into the side bays but will be diverted up to the openings in the monitor. Roof construction of the side bays is similar to that of the warehouses.

Roof construction of an unusual type, for the 42-ft. middle bay, consists of a $2\frac{1}{2}$-in. slab of concrete or gunite on I-beam purlins spaced 7 ft. on centers. Forms were placed close against the upper flanges, and wire netting was stretched from side to side, being supported clear of the beams by wire chairs. The concrete was then shot into place from above, as shown in one of the views. A test panel 11 days old, under a uniformly distributed load of 164 lb. per square foot, showed a deflection of $\frac{5}{8}$ in., with slight cracks on the underside. At 209 lb. the deflection increased to $1\frac{3}{8}$ in. and the cracks opened. On removal of the load the slab returned to normal position and showed no sign of injury on the top surface.

This work was done by the Cement-Gun Construction Co., of Chicago, which used not only its own equipment but some of that owned by the Dewey Cement-Gun Construction Co., in order to have ample capacity for keeping up with the framing of the building. Sometimes as many as 12 cement guns were at work.

CONCRETE ROOF OF MIDDLE BAY OF PIER IS BUILT WITH CEMENT GUNS

Operation Costs of Municipal Asphalt Plant

Portland, Oregon, Effects Large Saving Over Contract Methods—Plant Pays for Its Cost Three Times in Seven Months

CONSTRUCTING and repairing asphalt pavements with a municipal asphalt plant, during a seven-month working period, from Apr. 27, 1918, has saved the City of Portland, Ore., three times the first cost of the plant, according to the annual report of the city paving department. Comparison of itemized cost with the prevailing contract prices for such work shows a saving to the city of \$27,500 from an \$8800 investment. While there were some factors, such as advantageous contracts for aggregates which were highly favorable, so large a saving in a time of high wages and high prices for the other materials is thought to indicate considerable saving over other methods at all times. The following data are abstracted from the annual report mentioned above:

Conditions due to the war and high prices for paving work done by contract induced the City of Portland to build an asphalt plant of its own, and specifications were prepared for a plant with a capacity of at least 1000 sq. yd. of 2-in. wearing surface per eight-hour day. The installation of the plant, including the cost of machinery and remodeling and strengthening the dock so as to provide adequate foundation, required about \$8800. The plant as constructed has more than equaled the requirements, having turned out between 1000 and 1100 sq. yd. per day on several occasions.

Due to abnormal conditions, it was impossible to procure a new paving plant at a reasonable cost, so a plan was evolved to build it from several separate mechanical units, which could be obtained second-hand from contractors who had closed up their business because of the embargo on materials for public improvements. Care was taken in selecting this equipment to get it in good condition, and the plant as finally constituted is probably as good as a new plant would be, and has been obtained at less than half the cost.

The production of paving material at low cost was aided by several factors: First, on account of the central location of the plant and its proximity to water and rail facilities and sand and gravel bunkers from which these materials could be procured without hauling, cost for material was reduced to a minimum. Second, an annual contract had been made for sand and gravel at pre-war rates. Third, crushed gravel was substituted for crushed rock in the paving mixture, the former being about half the cost of the latter.

On the other hand, the war was responsible for several large increases in the cost of labor and material. The wages of the plant and street crews have increased about 33%, while the cost of asphaltic cement has been about 100% higher than before the plant began operation. It is felt that the conditions which have tended to the increase of the cost of production have heavily counterbalanced those tending toward cost reduction, and that the results obtained have demon-

TABLE I. SAVING TO CITY OF PORTLAND, OREGON, ON CONSTRUCTION ON NEW WORK DURING SEVEN-MONTH PERIOD

Location	Number of Square Yards Laid	Total Cost of Pavement	Cost per Square Yard of Pavement	What Cost per Square Yard Would Be by Contract	What Cost of Pavement Would Be by Contract	Actual Saving Over Contract Work
Terwilliger Blvd.	$22,464.00	$13,972.61	$0.622	$1.43	$32,123.52	$18,150 91
Nicolai Street....	1,584.20	1,351.32	0.858	1.43	2,265.41	914.09
Clinton Street.....	348.63	176.09	0.506	1.43	497.64	321.55
Mulberry Street..	628.00	567.09	0.903	1.43	898.04	330.96
Bridges.........	317.70	392.04	1.234	1.43	454.31	62.27
Crosswalks......	3,172.80	3,344.15	1.064	2.00	6,345.66	3,001.50
Totals	$28,514.70	$19,803.29	.....	....	$42,584.58	$22,781.28

strated that the prices charged for paving under the contract system now in vogue have been far in excess of the actual cost of such work.

An instance of this saving in cost is seen in the surfacing of Terwilliger Boulevard with a 2-in. wearing surface of asphaltic concrete. The contractors' estimate for laying this surface was $1.45 per square yard, exclusive of the cost of grading and scarifying the macadam foundation to a proper subgrade. The work as completed by the city cost $0.693 per square yard, which included not only the laying of the 2-in. asphaltic-concrete top, but also the scarifying and grading work, as well as the crushed rock used in rounding out foundation. The saving to the city on this one job of 22,464 sq.yd. was $18,150, or more than enough to pay the entire cost of two municipal plants of the type built. Table I shows the cost and saving to the city on new construction, during the period mentioned above.

Besides doing the work, the city repaired all cuts made in the pavements for public utilities and took on all maintenance work. On the maintenance work a saving of $3376 was effected, while on the repairing of cuts $1343 was saved. This made a total saving of $27,501 for the three classes of work. The cost of maintenance was reduced from contract prices of $2.87 per square yard to $1.44 per square yard.

The crew required to run the plant consisted of a foreman and three or four men, while the street force consisted of a foreman, a roller man, two rakers, and from three to six laborers. Table II gives itemized costs for the operation of the plant and laying of the pavement, which were under the direction of R. S. Dulin, engineer in charge of the paving department.

TABLE II. ITEMIZED COST FOR OPERATION OF MUNICIPAL ASPHALT PLANT AND PAVEMENT CONSTRUCTION

New Construction Work

	Total	Total per Square Item	Total per Yard Total
Plant Cost:			
Labor	$2,311.59	$0.081	
Fuel oil	632.51	0.0222	
Coal	99.25	0.0035	
Wood	61.68	0.0022	
Power	106.92	0.0038	
Paving materials	7,169.82	0.2514	
Total plant cost	$10,381.77	$0.3641	$0.3641
Hauling and transportation, including depreciation and interest and repair charge on trucks	2,990.71	......	0.1049
Street costs:

Cement Joints for Cast-Iron Water and Gas Mains at Vallejo, California

SATISFACTORY experience with the use of cement instead of lead for joints in cast-iron water and gas mains on the Mare Island project of the United States Housing Corporation at Vallejo, Calif., is reported by Philip Schuyler, assistant engineer, in a communication to Stephen E. Kieffer, project engineer, San Francisco, May 26. For a copy of the report, given practically in full below, *Engineering News-Record* is indebted to L. K. Sherman, president of the United States Housing Corporation, Washington, D. C.

The decision to use cement instead of lead was arrived at only after careful investigation of the results obtained in various cities in California during the past decade. The City of Los Angeles, under the direction of Mr. Mulholland, water-works superintendent, was practically the pioneer in the use of cement joints. The Pacific Gas & Electric Co. is now using cement exclusively in place of lead in the laying of all cast-iron mains in various cities in this state, and incorporated its specification in the official specifications for the utilities contract, as follows:

Pipe Joints—Pipe shall first be firmly set and well braced against jar or movement of the joints by careful backfilling between joints and bracing where necessary. Joints shall be carefully wiped out clean and dry. One braid or strand of hemp yarn shall be inserted in joint and very carefully and securely calked. A cement filler, composed of portland cement, with the addition of about 30% of carefully selected, clean, sharp siliceous sand, made into a stiff paste by the addition of water, shall be tightly pressed into the bell to within ½ in. of the face of the bell. A braid or strand of hemp yarn shall then be placed around the pipe against the cement in the bell and calked until the cement filler is firmly packed in the bell. The joint will then be wiped with cement paste, leaving same on a 45° level. The proportion of cement and sand in making paste and its consistency shall be as directed by the engineer. No water shall be allowed in or around pipes until cement is thoroughly set, which shall be determined by the engineer.

The contractor will utilize the services of the employees of Pacific Gas & Electric Co. in the actual work of installing and testing all gas mains and service connections.

Oakum or jute not being satisfactory for use with cement, we decided to use hemp rope, and from the Mare Island Navy Yard obtained some discarded slings made from ½- and ¾-in. tarred rope. These were old, dried out and very stiff, and after being cut into required lengths for our use were unstranded and the strands loosely retwisted and rolled by hand, the thickness depending on the size of joint to be calked. This particular kind of hemp rope proved so satisfactory that the company obtained a quantity for its own use elsewhere.

Great care was taken to see that all pipes as laid were solidly blocked so that there should be no movement of the pipe line during and after the making of the cement joints, and earth was tamped around and over the pipes between joints.

One strand, and sometimes two strands, of the retwisted hemp rope were inserted in the bell of the pipe, and this was rammed in hard by calking. A mixture of two parts cement to one part clean, sharp sand, with enough water added to make a dry paste which when balled and squeezed in the hand would barely exude moisture, was then inserted in the ball, pressed in first by hand until the bell was about half filled, and then calked as a lead joint would be calked, until the calking tool would barely penetrate the cement and the joint would ring. More of the cement paste was then inserted and the calking repeated, leaving the joint filled to within ½ in. of the face of the bell. A strand of the retwisted hemp rope was then laid around the bell, and this was calked in flush with the face of the bell. The joint was then wiped with cement paste containing sufficient moisture to mold, and it was beveled off.

Each joint, after being made, was kept wet by covering with pieces of old sacks, for at least 36 hours, after which the pipe line was slowly filled and allowed to stand under normal pressure, which was never greater than 70 lb., for at least two days, before testing.

Practically All Joints Water-Tight

In the first test 2000 ft. of 10-in. water main and 400 ft. of 8-, 6- and 4-in. pipe were included, and 50% of the joints leaked after they were subjected to the normal pressure. These leaks ranged from a slight sweating to a steady drip which filled the bell holes and covered the pipe. During the following three days most of the leaks stopped, and we decided to cover and backfill the whole pipe line, as the character of the ground was such that any leak would come to the surface, and let the pipe line remain under normal pressure for a week or two before putting on the test pressure of 125 lb. The dry hemp rope undoubtedly absorbed moisture and swelled, thereby stopping all leakage. All leaky joints took up with two exceptions, both of which upon being cut out and examined were found to have been very carelessly made. These were remade, and the line when tested showed no leakage.

A total of 20,770 ft. of 4- to 12-in. cast-iron pipe was laid on this project for water and gas distribution and only six defective joints had to be cut out and remade. When the pipe line could be drained the joint was remade with cement, but a few joints were cut out and remade with lead wool in order not to delay progress.

As it was necessary to pave the streets immediately upon the completion of the sewer, water and gas mains and services, the pipe lines were subjected to a severe test on account of the heavy teaming and heavy steam roller working on the subgrade, but not a single leak developed. The paving was completed in January and the first leak has yet to develop.

To anyone familiar with pipe laying and maintenance, using lead joints, this record should appear remarkable.

So far as we were able to ascertain from observation and cost records, the labor cost using cement joints should be slightly less than for lead joints. The cost of cement and sand per lineal foot on small sizes of pipe is negligible, and the money saved on this project was considerable, as the price of pig lead when this work was started was almost at its highest peak.

Teaming Industries Improve Service by Adopting Motor Trucks

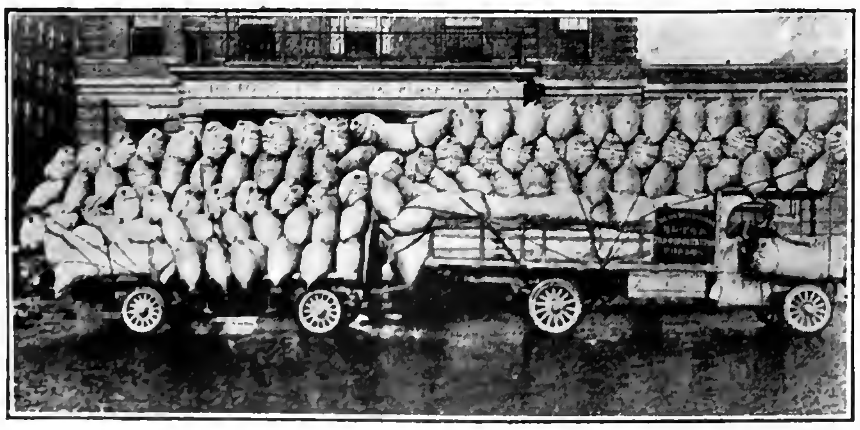
Large increases in business and much greater efficiency, both profitable to the teaming companies and more satisfactory to the merchants, have been effected in Boston, Mass., by the substitution of motor trucks and trailers for teams. In one case the tonnage handled by a teaming company was increased 300% in three years. Adaptation of the truck to hauling both heavy and light materials has also been demonstrated in this case.

An example of this expansion is seen in the business of the Youlden, Smith & Hopkins Co., which established its business in 1891 with two horses and a capital of $500. This business increased until, in 1916, five hundred tons of freight were handled daily within a radius of eight miles, an activity which required 150 horses and between 45 and 75 drivers.

In 1916 it was decided to substitute motor trucks and trailers for some of the horses, so as to increase the business by handling tonnage over a larger territory. A fleet of fifteen 5-ton trucks and three 5-ton trailers has been purchased to date, with the idea of supplanting 30 horses. The addition of the trucks has enabled the company to increase its activities so that, during the busy season, it now handles a daily average of approximately 1500 tons of freight within a radius of 30 miles. It is evident that the long-haul business would be impracticable with teams.

Not only has this change benefited the teaming company, but it is found that, due to greater efficiency, the service is more satisfactory to the merchant, who give preference to companies operating trucks. At the present time, only local hauling is done with horses; also, much of this is done with trucks. It is found that each truck purchased replaces four horses, besides increasing both the local and interurban business.

A specially designed Troy trailer, attached to a large truck for the economical hauling of bulky materials, is shown in the accompanying illustration. This trailer



MOTOR TRUCK AND TRAILER HAULING BULKY MATERIAL FOR BOSTON TEAMING COMPANY

has a chassis 16 ft. in length and a capacity of five tons. In the picture it is loaded with sacks of wool. The cab roof of the Mack truck is arranged with an upright so that it may be utilized, and the bags are securely bound on with ropes. While it would seem that in turning there would be trouble with the bags over the coupling, it is stated that no particular difficulty has been experienced, doubtless because there is a large amount of give in the sacks of wool.

Surface Aggregate or Fineness Modulus for Concrete

Professor Duff A. Abrams Defends the Fineness-Modulus Theory of Proportioning Concrete and Gives His Objections to the Surface-Area Theory Proposed by L. N. Edwards

Following the presentation in "Engineering News-Record," of Apr. 17, 1919, p. 758, of an abstract of Bulletin No. 1 of the Structural Materials Laboratory, Lewis Institute, which is an exposition of the fineness-modulus theory of concrete proportioning developed by Prof. Duff A. Abrams, L. N. Edwards, the proponent of the surface-area theory of concrete proportioning, submitted certain comments on Professor Abrams' remarks about the latter theory. This letter and a reply from Professor Abrams are given below. The reply contains some new data from the Structural Materials Research Laboratory, as well as definite criticism of the surface-area method—EDITOR.

Surface Area Method of Proportioning Concrete Is Defended

BY L. N. EDWARDS

Senior Highway Bridge Engineer, Bureau of Public Roads, Washington, D. C.

THE reference in Professor Abrams' article to the surface-area method of proportioning appears to the writer to be subject to question; more especially so, since his own investigations have shown its efficiency for both laboratory and field use.

It is not quite clear just what is meant by the statement, "Our studies have shown that surface area is not a satisfactory basis for proportioning aggregates," since the surface-area method is not confined to the proportioning of the aggregatés, but instead is adapted to the proportioning of all the ingredients of the mix, including the water content. Table II of the article above-mentioned does not appear to the writer to offer evidence tending to disprove the fundamental principles of the surface-area method, but rather to add emphasis to the important role of the water content of the mix in the determination of the ultimate strength of the concrete. Incidentally, Table II calls attention to a rather important detail of concrete making to which the fineness-modulus method gives scant consideration.

Granting for the present the correctness of the surface areas as recorded in Table II, then, since the quantities of cement and water were maintained as constants throughout the entire series of tests, it naturally follows that, by reason of the variations existing in the surface areas of the aggregates to be moistened, the quantity of water combining with the cement to form the cement matrix is correspondingly changed. Very small variations in the water content of the cement matrix, at the time of mixing, produce radical changes in its strength, and other physical properties when it has become fully set. "However, it is only the water which goes to the cement (that is, exclusive of absorbed water) which affects the concrete strength." Likewise, this change in the consistency (plasticity) of the concrete is fully recognized in Bulletin No. 1 of the Lewis Institute, but this portion also of the original paper was not incorporated in the *Engineering News-Record* article. Its importance appears to justify its inclusion here:

"The grading of the aggregate may vary over a wide range without producing any effect on concrete strength, so long as the cement and water remain unchanged. The consistency of the concrete will be changed, but this will not affect the concrete strength if all mixes are plastic." The requirement that the concrete be "plastic" when mixed will be referred to further on. However, it may be said here that the above quotation, together with the preceding one from the same source, contains the kernel of the cement-water ratio idea.

Concerning the surface areas recorded in Table II, the writer has endeavored to check about one-third of the entire list. For this purpose unit areas, adapted to Tyler standard sieves, were used. These areas were derived from the writer's tests, described fully in a paper, "Proportioning the Materials of Mortars and Concretes by Surface Areas of Aggregates." (See "Proceedings" of the American Society for Testing Materials, Vol. XVIII.) The fact that a very marked difference has been found between his results and the tabulated areas leads to the conclusion that the latter were determined by a somewhat different method.

For a proposed concrete structure, the consideration of possible sources of supply of aggregates frequently involves the laboratory examination of the concrete-making qualities of two or more different aggregates varying in their sieve analyses and other physical properties. The field condtions attending the mixing, handling, placing and finishing of the concrete, as well as ultimate strength, toughness, etc., of the concrete produceable from them, require that the relative merits of these aggregates be determined under the conditions characteristic of the surface-area method. Most assuredly, those conditions which tend to produce variations in the relative plasticity and the final strength of the cement matrix should be eliminated. In the tests described in Table II, uniformity of strength was the single object sought. Uniformity of plasticity and toughness were not considered.

The writer does not desire to create the impression that the fineness-modulus method is radically different from the surface-area method; on the contrary, he has failed to discover wherein these methods are at variance, although it may truly be said that they approach the problem of concrete design from quite different angles.

Tests Do Not Bear Out Surface-Aggregate Method

BY DUFF A. ABRAMS

Professor in Charge, Structural Materials Research Laboratory, Lewis Institute, Chicago

IN DESIGNING concrete mixtures, three elements must be kept in mind: (1) Workability; (2) strength, or other desirable property, and (3) cost. In usual circumstances, each of these three factors is an absolute limitation on the makeup of the concrete. If cost were no item, concrete of any desired strength and workability could be secured by using rich mixtures. In order to reduce the cost to a minimum, we use as much aggregate as feasible. The degree of workability required depends on the nature of the work and the methods used in handling and placing. The workability of concrete is one of its prime advantages and a certain degree of workability is absolutely essential. In order to reduce to a minimum the cost of handling and placing, a satis-

factory degree of workability may be secured by using a little more water than is necessary, and an aggregate of somewhat greater fineness than that known to produce maximum strength of concrete. In designing concrete mixtures, the engineer must work out a nice balance between the strength, cost and workability in order to secure an economical building material.

It has been pointed out that the function of water in concrete is twofold: (1) To hydrate the cement; (2) to form a plastic mass.

The quantity of water required to hydrate the cement has not been definitely determined; it is probable that not more than 25 to 40% of the water in ordinary concrete is necessary for this purpose.

Tests made in this laboratory have shown that with given materials and conditions of test the quantity of mixing water used determines the strength of the concrete so long as the following conditions are observed: (1) Concrete is plastic with the method of placing used; (2) aggregate not too coarse for quantity of cement used; (3) mixture not so wet that all water cannot be held by the concrete.

Regardless of the size or grading of the aggregate, the amount of cement or the consistency of the concrete, the "water-ratio" may be used as a measure of the strength of the concrete. In other words, it makes no difference *why* the water-ratio is changed; the fact that it *is* changed within the limits stated above produces a definite result. Other properties of concrete, such as wearing resistance, modulus of elasticity, etc., have been found to follow similar laws.

Captain Edwards has not given sufficient weight to the fundamental relation between the water content and the strength of concrete. He states in his original paper that "the surface-area method of proportioning concrete assumes as its basic principle that the physical properties are primarily dependent upon the relation of volume of cementing material to the surface areas of the aggregates." It seems to me that the tests reported fail to bear out this assumption. On the other hand, many different series of tests made in this laboratory have shown that the quantity of cement is *not* a criterion of the strength of the concrete unless at the same time we take into account the quantity of water used. A 1: 9 mix may be as strong as a 1: 2 mix. In other words, it is the *ratio of water to cement* that determines the strength of the concrete. Table III shows one way in which the quantity of cement may be varied 400 to 600% without producing any appreciable effect on strength so long as the water-ratio is constant. Much greater variations in cement content could have been made had it seemed desirable.

The "water formula" for concrete cannot be reduced to the simple form given by Captain Edwards, if it is to be of general application. The water formula given in Bulletin No. 1 takes account of the following six factors: (1) Relative consistency of concrete (workability factor); (2) normal consistency of cement; (3) the mix (volume of cement); (4) size and grading of aggregate (measured by the fineness modulus); (5) absorption of aggregate; (6) moisture contained in aggregate.

Another term is necessary when an admixture is used. The items, with the exception of (1) and (4) can be readily determined for given materials. The amount of water required under (1) will depend on the nature of the work, the method of placing the concrete, etc. Any method which will give a *proper* distribution of the water due to the size and grading of the aggregate should give satisfactory results. This Captain Edwards has endeavored to accomplish by means of the surface-area factor, while we have used the fineness modulus of the aggregate.

Where the Two Methods Differ

The fineness modulus is the sum of the percentages in the sieve analysis of the aggregate, divided by 100. Sieves from the Tyler standard screen scale are used. The percentages are expressed in terms of the quantity of aggregate by weight or volume *coarser* than each of the sieves. For a particle of a given size the surface area and the fineness modulus bear a direct relation to each other, since they are both simple functions of the diameter. The surface area varies as the square of the diameter, while the fineness modulus is a logarithmic function of the diameter. The relation is not so simple when we come to deal with graded aggregates. The discrepancy in this case becomes so great that both of these methods cannot be correct for a wide range of conditions.

A further discussion of the quantity of water required on the basis of the grading of aggregate may be of interest. The plasticity or workability of the finished concrete is the only criterion which can be used in comparing the water requirements of different mixes, gradings, etc. We have used the "slump" test for this purpose. This consists of molding the 6 x 12-in. cylinder in a smooth steel form by puddling the concrete in 4-in. layers with a ⅝-in. steel bar, leveling off with a bricklayer's trowel, then immediately removing the form, without opening it, by a steady, upward pull. The shortening of fresh concrete from its original length, measured in inches, is the "slump."

The water which must be added, due to the presence of the aggregate, aside from that absorbed, may be divided into two portions: (1) To form a surface film on aggregate; (2) to make a thin cement paste which will produce a plastic mix with the aggregate. The total quantity of water required for this purpose can be determined experimentally by measuring the additional water necessary to produce a given plasticity in a concrete mixture as compared with that required for neat cement. By using different quantities of aggregate and different sizes and grading we arrived at the term, $0.30/1.26^m$, in our water formula which takes account of this factor. (It will be noted that this term gives a relation between water and fineness modulus similar to the water-strength curve in Fig. 1 of Bulletin No. 1.) The total quantity of water required for this term in an ordinary concrete mixture is about 8% by volume of concrete, or 40 to 50% of the total. This quantity is known to give satisfactory results. There is no reason why the water necessary to thin the cement paste should not be charged to the cement instead of the aggregate; however, the latter method seems more logical, since it is the presence of the aggregate and its size and grading that necessitate the addition of water to produce a mix of the same plasticity.

How Much Water Does Aggregate Take?

Let us see how much the quantity of water which must be charged to the aggregate (aside from that absorbed) is dependent upon surface area. Earl Pettijohn has shown (*Jour. Am. Chem. Soc.*, April, 1919)

that the thickness of the surface film of standard Ottawa sand is 0.00003 in. at the point when free water begins to form. This means that 18 cc. (about 1/20 pint) of water would be required to produce the surface film on a cubic foot of standard sand and a much smaller quantity for ordinary concrete aggregates. The water required for this purpose is negligible. In other words, practically the entire quantity of water necessary on account of size and grading of aggregates must be charged to thinning the cement paste.

Ordinary mixes require water-ratios of 0.75 to 1.00; the value for neat cement with a normal consistency of 23% by weight is 0.35. In other words, the cement in concrete contains two to three times as much water as that required for normal consistency. It is the dispersion of the cement particles which results from the addition of water that is responsible for the rapid reduction in strength found in the wetter mixes.

How must the thinness of this paste be varied in order to produce a plastic mix with aggregate of different size and grading? Upon thinning the paste by adding water, we observe the following phenomena: (1) Increased plasticity; (2) change in volume.

The increased plasticity arising from adding water needs no demonstration. The volume of paste is first reduced, then increased as water is added to cement. Table I herewith shows the effect with a standard cement weighing 94 lb. per cubic foot:

TABLE I. VOLUME OF CEMENT PASTE

Water Added to One Volume of Dry Cement: Water-Ratio	In Terms of Normal Consistency	Volume of Cement Paste
0.35	1.00	0.87
0.40	1.14	0.89
0.50	1.43	0.98
0.60	1.71	1.06
0.75	2.14	1.20
1.00	2.90	1.42
1.50	4.3	1.93
2.00	5.7	2.40
3.00	8.6	3.20

That the *volume* of paste is an important factor in producing plasticity of mix can readily be seen from the fact that plasticity can be increased by increasing the quantity of cement and using relatively less water; in other words, a given degree of plasticity is produced by a low water-ratio for a rich mix and a high water-ratio with a lean mix. Just what effect the actual *quantities* of paste have on workability under the extreme conditions of mix, etc., has not been determined.

Current theories of concrete are generally based on the idea that the quantity of paste is dictated by the voids in the aggregate, with a certain surplus. Four weaknesses in this theory may be mentioned: (1) The voids in the aggregate can be varied widely without producing any change in the quality of concrete; (2) the grading of aggregate which gives greatest strength in concrete gives higher voids than are found in other gradings of lower strengths; (3) concrete of highest strength may contain visible voids; (4) the strength and other desirable properties of the concrete depend on the *quality* of the paste and is little affected by the *quantity*, so long as we have sufficient to produce a workable mix.

The influence of the cement-water mixture on the plasticity of concrete is, then, a function jointly of the plasticity and volume of the paste. We have seen that the strength is a function of the water-ratio (volume of water to volume of cement) and that the strength of concrete decreases as the water-ratio increases; hence, in order to secure the highest grade of concrete at the lowest cost it is necessary to secure a given condition of plasticity with a minimum water-ratio. What condition with reference to the size and grading of the aggregate will give the desired result? It is obvious that this is a most complex relation if we consider the almost infinite variety of sizes and gradings which may be made from a single aggregate. Captain Edwards has used the surface areas as a satisfactory measure. It seems to the writer that the radius of curvature of the particles and the number of points of contact (or near contact) between adjacent particles are the factors which are primarily responsible for the additional water which is necessary due to the presence of the aggregate. Both of these factors are functions of the diameter; the radius of curvature is one-half the diameter if we assume that aggregate of spherical form is being used. Since particles of all sizes are mixed at random, and there is no systematic arrangement, it is impossible to analyze the problem in a way that will enable us to compute the number of points of contact. The only practical method, then, is to determine the relation by trial. The fineness-modulus method was arrived at in this way. It was discovered from a study of mortar strength tests of about 1000 different sands mixed to a uniform plasticity, and stored and tested under uniform conditions.

The water formula given in our Bulletin No. 1 is of a rational form and can be applied to any combination of concrete materials. Its development was an evolution extending over several years. These formulas were numbered in the order of their derivation as they were modified from time to time on the basis of experience. The above formula is No. 11. It is based on the experience of many thousand tests. I do not mean to be understood as believing that this formula is exact and will require no further modification. On the other hand, subsequent experience may dictate certain changes.

The formula has been subjected to many severe tests by applying it to aggregates of the most diverse character. A recent series of tests using four different coarse aggregates (graded No. 4 sieve to 1½ in.) and the same sand gave the following results (Table II) for 1:4 mixes:

TABLE II. STRENGTH OF CONCRETE FROM FOUR AGGREGATES

Coarse Aggregate	Compressive Strength (Pounds per Square Inch)
Pebbles	3,620
Crushed limestone	3,830
Crushed slag	3,750
Crushed granite	3,850

Tests were made on 6 x 12-in. cylinders at the age of three months. Twenty-one different gradings were used for each coarse aggregate. Specimens were stored under two conditions. Each value given above is the average of 105 tests. The water for these concretes was proportioned by the formula given above. The fact that with similar gradings and water properly controlled we secure uniform plasticity and strength is a severe test of the formula, when it is considered that we are comparing spherical and crushed materials of widely different characteristics. The absorption of the aggregate was also different in each case. Many serious errors have been made by experimenters in comparing the concrete-making qualities of different aggregates. The wide variations reported in the strength of the concrete made from different materials can almost invari-

ably be traced to failure to take account of differences in size or grading, and to neglect of the absorption of aggregates.

The sand-mortar tests in Captain Edwards' paper, which were mixed with 1 volume of cement for each 13 sq.in. of calculated surface area of the sand, gave mortars of fairly uniform strengths at three different ages. These tests are interpreted as proving that the surface area of the aggregate is a proper basis for proportioning mortar and concrete mixtures. It is the writer's view that the uniformity in strength is due to an entirely different cause. Since both the water and cement were proportioned on the basis of the surface area of the aggregates, he obtained a uniform water-ratio, which is solely responsible for the uniform strength. This is the result to be expected so long as all of the mixtures were plastic and none of the aggregate gradings was too coarse for the quantity of cement used.

Tests Do Not Check Surface Method

It is unfortunate that it was not feasible to include in our Bulletin No. 1 all of the data on which the conclusions were based. It is the writer's belief, however, that the tests given in Table 2 of the bulletin bring out a fatal limitation of the surface-area method of dealing with proportioning of aggregates. Twenty-seven different gradings of the same aggregate were used. The gradings were made to vary over a wide range, but had one property in common; that is, the fineness modulus was uniform. They were mixed with the same proportions of cement and water. The strengths for two different consistencies showed a mean variation from the average of about 3%, and a maximum variation from the average of about 10%. The corresponding values for surface areas are 34% and 110%, respectively. If the water proportioning of these tests had been based on Captain Edwards' formula the water-ratios of the concrete would range from 0.39 to 0.57, an extreme variation of 69%, and would have made a very great difference in the plasticity of the concrete. It is true, as stated in Captain Edwards' letter, that these tests were made with a view to determining whether or not a uniform strength of concrete was obtained with such wide variations in the sieve analysis of the aggregates. However, the plasticity or workability of the concrete did not differ materially.

The surface-area values in our table were calculated from the diagrams given in Captain Edwards' paper. It was necessary to estimate the areas of the sand particles below the 100-mesh sieve, and wide variations may be due to this cause. In certain of the tests as much as 10% of the aggregate was sand finer than the 100-mesh sieve. The surface area of this portion which we must estimate or neglect entirely is probably considerably greater than the entire surface area of many other gradings in the same group. The quantities of water given by Captain Edwards' formula are only 60 to 70% of those required for the materials used in this laboratory. It was impossible to mix concrete using the water given by his formula.

Table III herewith gives the results from a portion of some recent tests in this laboratory. Two leaner and two richer groups of mixtures are omitted. The quantity of materials required for each specimen, beginning with the 0-1½ in. aggregate and a mix of 1:2½:5, 1:2:4, 1:1½:3, etc., was calculated. The coarser sizes of aggregate were dropped in turn, but we retained exactly the same quantity of cement and water. The final mixes in terms of volume of cement and total aggregate are given in Col. 2 of the table. It is obvious that the richer mixes in each group are much more plastic than the leaner ones, and that equal workability was not secured. As in all other tests in these investigations the concrete for each cylinder was mixed separately by hand. Each value is the average of five tests made on various days. The second series of tests is not yet completed; however, the tests which have been made show a greater uniformity in strength than those in Table III, due to slight readjustments of certain constants in the water formula. These tests confirm the conclusion based on many other series; Namely, that *the widest variations may be made in the mix, consistency, and size of aggregate without any change in strength so long as the water-ratio is unchanged,* and the above limitations are not violated.

It seems to the writer that any comparison of the surface-area and fineness-modulus methods must be reduced to the following two factors: (1) Which rests on the more sound experimental basis? (2) Which is the more simple to apply?

As stated above, the whole question of the comparison between the two methods resolves itself into that of determining which will give the better distribution of water in a mix, so far as the size and grading of the aggregates are concerned. Both of these methods make use of the sieve analysis of the aggregate. However, it seems to the writer that there is more variation in the underlying principles than that suggested in the last paragraph of Captain Edwards' letter.

It appears to the writer that the following disadvantages accompany the use of the surface-area method: (1) Areas of the finest particles of sand cannot be computed; (2) crushed aggregate requires a greater quantity of water for the same grading than pebbles of a spherical form; (3) if the surface-area method were strictly interpreted it would require separate treatment for practically each kind of aggregate; (4) the method requires laborious computation, with the resulting chance of error; (5) it is not clear how the method can be applied to the simplest problems which arise in the course of designing concrete mixtures; for instance, to determine the best proportions of given fine and coarse aggregates for a concrete mixture; (6) it has not been shown that there is any theoretical reason why the surface-area method gives more nearly correct results than other methods which have been proposed.

If the surface-area method is correct, it would seem to be a serious fault that the areas of the finest particles cannot be satisfactorily dealt with. It seems probable that in extreme cases the areas of the particles finer than the 100-mesh sieve would be in excess of the combined areas of the coarser sizes. Our experience indicates that the quantity of water required for these fine sands is not in proportion to the amount that would be suggested by the surface areas.

The area of a tetrahedron is 25 to 30% greater than that of a sphere of the same volume, or one having a diameter equal to the height of the tetrahedron. Our experience in testing concrete made of crushed aggregates as compared with rounded pebbles does not indicate that there is any discrepancy in the quantity of water required, as would be suggested by the surface-area method.

TABLE III. EFFECT OF SIZE AND GRADING OF AGGREGATE AND CONSISTENCY OF CONCRETE

Compression tests
Age at test, 28 days
Sand and pebble aggregate

Six by 12-in. cylinders, hand-mixed concrete
Stored in damp sand; tested damp
Each value is the average of five tests made on various days

* Fineness modulus of aggregate.
† Yield was calculated on the basis of the original volume of dry aggregate.

The computation of surface-areas begins at practically the same point where the determination of the fineness modulus ends. There appears to be little room for question as to which of the proposed methods is the more simple in application.

No doubt, the surface-area method could be worked out so that it would apply over a limited range. In fact, almost any function of the size of particle could be used in this way. This would be equivalent to representing a portion of the curve by a line or by an arc of different curvature.

It is unfortunate that the wording in our Bulletin No. 1 was such as to permit the interpretation which is placed upon it by Captain Edwards in the third and fourth paragraphs of his letter. The thought the writer meant to convey was not at all the meaning that Captain Edwards finds in this report. The purpose was to indicate that the *size* of the aggregate may vary over a wide range without producing any effect on the concrete strength, so long as the concrete and water remain unchanged; for instance, as in Table III, herewith. The confusion arises from the use of the term *size* and *grading* interchangeably and to the use of both of them in a multitude of different senses. It was not intended that this statement should apply to the case of aggregates having the same fineness modulus, such as those given in Table 2, Bulletin No. 1.

Correction in Writer's Title

H. Y. Carson, lately captain and sanitary engineer, American Red Cross Commission, author of the article "Ancient, War-Time, and Present Water-Supply in Jerusalem," *Engineering News-Record* of June 5, 1919, p. 1092, is now with the American Cast Iron Pipe Co., Birmingham, Ala., and not with the Central Foundry Company, as indicated incorrectly at the head of the article.

New Etching Process for Studying Structure of Steel

Does Not Require Polished Surface, But May Be Used With Emery Finish—Prints Made by Ink and Copying Press

A USEFUL improvement in methods of etching sections of steel to study the quality and internal structure of the metal has been made by J. C. W. Humfrey of Sheffield, and is reported by him in a paper read last month before the Iron and Steel Institute, under the title "Macro-Etching and Macro-Printing." The value of the method lies in its ease of application; instead of requiring a finely polished surface to prepare for the etching (with present methods a coarser-grained surface is not adequate, in view of the delicacy of the etching) it can be applied to surfaces having an emery-paper finish only. Furthermore, the etching gives such a degree of relief that prints can be made by means of printer's ink and copying-press methods. Specimen prints included in the paper just mentioned show that the marks traced out by the impurities in the steel which give rise to the differences of etching are sufficient to portray the mechanical structure of the metal very perfectly. Thus, ingots, punched shell blanks and the like show clearly defined structure markings.

Humfrey's etching solution is a modification of Heyn's reagent (copper ammonium chloride) made by adding strong hydrochloric acid. The most satisfactory composition was found to be 120 g. of copper ammonium chloride, 50 cc. of concentrated hydrochloric acid and 1000 cc. of water. This solution is poured on the surface to be etched, which is placed horizontal, and is renewed frequently, so that a film of fresh solution is always in action. A satisfactory relief effect is obtained in from 20 min. to one hour.

It is preferable to start the etching with a neutral

solution and continue with it until the emery-paper scratches are all eaten away. Then, in successive applications of the acid solution, the acidity of the reagent is gradually increased up to the maximum. By starting with neutral solution, the copper which is thrown down on the iron is given a loose or flocculent nature, so that it can be wiped away, while the acid solution tends to produce an adherent plating of copper. For this reason, whenever the solution and the copper are wiped off for the purpose of examining whether a sufficiently deep etch has been obtained, the etching is started again with the neutral solution, subsequently acidified in successive stages.

When a surface so etched is inked with a printer's roller a print can be made from it in a copying press. Coated paper and a rather hard pad give the best result.

The effect of the acid solution is to attack most vigorously the purer parts of the metal, which solidified first. All areas containing marked amounts of impurity are more resistant to the reagent and show on the finished plate in high relief. The chief impurity having the effect of increasing the resistance of the steel to the etching fluid is phosphorus, and in a sense the prints obtained are maps of phosphorus distribution in the metal, just as bromide-paper prints give maps of the sulphur distribution.

Presidential Address at Convention of Civil Engineers

Fayette S. Curtis Outlines the Duties of the Engineer and Reviews Past Accomplishments—Promises for the Future

DIGRESSING somewhat from the trend of former addresses, Fayette S. Curtis, in his presidential address June 17 at Minneapolis, Minn., at the first convention of the American Society of Civil Engineers held after two years' interruption by the war, spoke of the duties of the engineer, what has been accomplished in the past by the society and what is to be accomplished in the future, the personal application necessary to make work successful, and the distinction to be gained through uprightness and honest labor. The address, practically in full, follows:

It is quite probable that some of you have often been asked the question, "Do you recommend civil engineering as a profession?" and I assume that generally an affirmative answer has been given. The civil engineer, when thoroughly fitted for his profession, immediately becomes useful to society and the world of materiality. He is prompted by the wants of society, and is constantly originating other wants by the improvements he introduces. He is also creative, and his profession is not mortgaged to power or influence, but stands firmly on its own foundation—encouraged by world-wide influences.

His duty consists in designing, arranging, and building structures or machines which require the immediate superintendence of those who are acquainted with not only the principles but the practice of construction; for engineering is a branch of knowledge that takes its place both among the sciences and the arts.

Therefore, to be eminent in his profession, or any branch of it, he should be able, not only to design and plan, but to supervise construction. Those who have only the knowledge of how to design and plan, and are unable to execute, become confused in meeting the many contingencies which arise.

Requires Acquaintance With Sciences

The profession, embracing as it does almost every kind of construction, requires a very extensive and general acquaintance with other sciences, in order that the engineer may be qualified to accomplish successfully the various works on which he may be engaged, and to overcome those difficulties which frequently arise unexpectedly in the progress of his work, and, but for that knowledge and talent, threaten its final success.

Thomas Telford, in his "Descriptive Narrative of his Professional Labours," has said:

"How can a man give judicious directions unless he possesses personal knowledge of the details requisite to effect his ultimate purpose in the best and cheapest manner? It has happened to me more than once, when taking opportunities of being useful to a young man of merit, that I have experienced opposition in taking him from his books and drawings, and placing a mallet, chisel or trowel in his hand, till, rendered confident by the solid knowledge which experience only can bestow, he was qualified to insist on the due performance of workmanship, and to judge of merit in the lower as well as the higher departments of a profession in which no kind or degree of practical knowledge is superfluous. For this reason I ever congratulate myself upon the circumstances which compelled me to begin by working with my own hands, and thus to acquire early experience of the habits and feelings of workmen; it being equally important to the civil engineer, as to naval or military commanders, to have passed through all the grades of their profession."

It is no doubt true that many men have gained prominence in their profession by individual effort—practicing and studying at the same time, with a view to acquiring a full knowledge of all necessary scientific principles. Students are required to spend a certain time in acquiring technical knowledge, but must not then think they are engineers in the broad meaning of the term, capable of constructing and being responsible for engineering work, as that is a false idea.

No one can doubt that the addition of the natural sciences to the old-time arts course has greatly enriched it, and the sciences are now undoubtedly the most important part of a liberal education; but there is another side, which we cannot ignore, and that is, that, after all, the great object of a good education is not so much the accumulation of knowledge as the development of mental power in the individual.

The tendency toward scientific and practical education is no new thing. Men have come to see that the first mental training can be made more effective by solving physical problems than by studying the dead languages, because as much true value can be obtained in the study of nature as in the study of man's conception of nature. First knowledge is more satisfactory to the best of minds.

Specialization Necessary

The profession has become so diversified that after having secured a good fundamental training it would be worth serious consideration to take up a single branch of engineering practice, as it can hardly be expected that the civil engineer will become proficient in every branch. He would be better able to give his best endeavors to attaining the highest proficiency in some particular line, and, at the same time, grasp or understand in a general way the subjects which may relate to the several kinds of works, as the whole subject is so broad that it would be vain to attempt to understand them all in all their details.

Ambition to obtain as great a knowledge as possible is to be admired and encouraged, but to attain the highest standard in one branch is more commendable than to attempt to reach special eminence in all, as the student will be apt to find himself oppressed with a weight which he is not capable of sustaining, and this will be very likely to result in utter failure.

The professional man should not make the mistake of thinking that he can reach the top in an unconcerned and idle manner, believing that by some easy process he will

reach and hold it. The structure on which he stands must be constructed by piece and parcel, every member thoroughly tested by a gradual and difficult process; he must experience all the difficulties, trials, and troubles to be met on the way, in order to support and sustain him at the higher elevation to which he aspires. To such the doors to success are open. Work seeks the best hands, as naturally as water runs down hill, but seldom seeks one whose only recommendation is that he needs it. If he is not willing to go slowly through the maturing process of time, through patient work, by steady application step by step preparing himself for the work ahead, which has made men prominent and efficient in their profession, then, alas, the result is doubtful. It is like the student who prepares his education for future advancement. He goes from grade to grade until he is master of the science on which he has to build, taking no upward step until the last has been tested and found not wanting in any characteristic which will sustain him and serve him to build on for the future.

Facing New Conditions

New problems are all the time arising. The tremendous growth of our complex industrialism means the facing of new conditions, that we may overcome new difficulties and enjoy new benefits. Therefore, there is only work to face, and it should be met with a spirit characteristic of the creator of science, and thereby much may be accomplished.

There is no success without hard and earnest labor. Never balk at a few obstacles, but hang on with all your might; this, in the end, will give success. It is true that many experiments will have to be made, but there can be no doubt of ultimate success if our aim is a determination to succeed and we do not become discouraged.

As we look back, even over a short time, how often have we said to ourselves, after completing some important structure, "This should last for many years—we have reached the limit;" but within a comparatively brief period have we not seen that structure replaced by another, larger and more expensive, which has been demanded by the growth of business? We have not stopped building, nor have we come to the time when we have built sufficiently for the future, and we never will, as long as the richness of this country is undeveloped and its physical and financial growth continues. To stop this great advancement, which the people continue to make, would be death. Then, does it look as though there was not a future for the engineer who has integrity and perseverance, as he is and must be the practical foundation or basis for all which we are to build, in order to accomplish a higher and nobler position in society?

The work of the engineer is the foundation on which rests the growth of this great republic, not only physically but financially. He is one of the prime factors, and could not by any possibility be dispensed with. We are not an organization which threatens to pull down and wreck or destroy what we have built, but an educational organization, and hope to get the necessary recognition of our rights through education. No doubt the engineer has often had his line of procedure curtailed by some power having authority to suspend or discharge at will, at the pleasure of some controlling power, ignorant, and with no understanding of the conditions or the difficulties the engineer may have to meet, and without the least knowledge of engineering subjects.

Civil engineering is ages old, but has always shown a steady progression, possibly not as to more substantial work, but certainly in the facilities provided in machinery to do its work. As to its beginning, I will not undertake to say, but will only refer back to those times of which we may have knowledge, and ask if the great work done is not a credit to the scientific ability of this profession? But what is the future to be? Does it depend on those who are coming into this society—educated, experienced—to show to the world that they can and will continue to build and improve the financial and social conditions? For a determination we must wait on time.

Is the engineer being benefited by his connection with this society? It has been said that the society is becoming less democratic and more conventional, or, in other words, is not taking sufficient interest in, or having proper regard for, its members, and, therefore, they are without the opportunities or advantages which they might gain in local societies. This society has grown to such an extent that contact personally with all its members is not possible, but the interest and devotion and brotherly love of its members are just as great as ever. The information in the different papers by the most prominent engineers of the country, presented and distributed, is of the greatest importance to the members of the society. As the society grows, this information increases, and the papers are more numerous and contain information and knowledge which cannot be obtained except through the parent society. If not, why are so many engineers anxious to affiliate themselves with this society? They know it gives them prestige the world over, and sets a standard which has been passed upon and approved by the highest of professional men. Our constitution requires that standard to be higher than that of any of the local societies.

The society has not only grown in numbers, the increase within the last ten years being 85%, but has increased in influence in the estimation of the public and the world at large; our members are looked up to as the leaders in the engineering profession. Then, who can say that it, as an engineering society, has depreciated, gone back, or fallen off one iota from its former standing? On the contrary, it has grown steadily stronger and stronger. Its members have become of such strength, in the material and financial upbuilding of the Government, that they are indispensable.

Therefore, we must not permit ourselves to forget the obligation we owe to the founders of this society, the men who gave their time and talent in creating an organization which has proved to be of untold benefit to the engineering profession. How, then, are we to repay them, if not by giving to the society our support and assistance, promoting good fellowship among its members, encouraging its officers, and giving a helping hand to the future engineer who comes into the society, passes up through the different grades of experience, and is seeking information? Let us all do something in the interest of the society, and thereby broaden its influence and add to its high standards of proficiency.

We certainly cannot help by creating dissensions among the members, or becoming dissatisfied with the earnest labors of those whom we select to bear its responsibilities, or in getting the idea that we are connected with this society wholly for what we can get out of it. No matter how much we give, we can never repay the society for the benefits we have received.

Future of High Honors Possible

The engineer has designed and built many a monument which will endure for ages as a testimonial to his proficiency and skill. We need not go back many years to find members who have won the highest engineering distinction and whose names are ineffaceably engraved on the enduring pages of history. We know who they are and what they have accomplished. Even before this society was organized, we find the names of engineers who achieved everlasting remembrance through their exceptional ability. Therefore, I would say to engineers, but more particularly to the younger members of the profession, that there is a future for them which, if taken advantage of, will insure the highest honors possible to be obtained.

By him who is in the prime of life and in the possession of health, strength, and knowledge of the arts and sciences, much may be accomplished. Therefore, never give up. Think, work and suffer, that in this life you may gain something which will place your name upon the highest pinnacle of fame.

Many of our members have been engaged in the late war, and their work, in the construction of yards, docks, cantonments, and the reconstruction and building of bridges, roads and equipment, both in this country and on the other side of the Atlantic, thus making it possible to take care of millions of troops, was the most important factor in bringing the war to a successful termination. All of this has been done in such short time as to bring out comment and praise from the whole world. Why should not the

engineer have his full due and credit for the ability he has shown, not only at critical moments during the war, but in the accomplishment of things at other times?

We are living in an age in which we possess all the information as to what has been done for many years, all of which we ought to profit by. The conditions change, the opportunities grow greater. This world is growing in its necessities almost beyond the imagination of the present generation. The country is being developed so that every state in the Union is increasing in wealth and prosperity. Greater facilities are needed to accommodate its growth. And yet some say there is no future!

Work of Other Societies

The work of other engineering societies or organizations should also be mentioned. They have all done their part in building and developing the great industries of the world. All are working toward the same purpose, creating, building, and improving the facilities on which the prosperity of the country depends. This is illustrated by the establishment of Engineering Council, composed at present of representatives of the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the American Society for Testing Materials, for the purpose of giving more strength to the profession and obtaining greater recognition for the engineering arts and sciences.

Why should we not go farther, and even take our position in Governmental affairs? Is it the political cloud that casts a shadow over us, so that our practical ability does not get the proper recognition in Government affairs; or is it our modest, indifferent way of being satisfied with our present condition? We should rise to the occasion, demand our rights, and a proper recognition by the people generally, with the idea that we are not only to advance the engineering arts and sciences but to fill the positions under this general Government which require the knowledge of how to govern, each according to his ability.

The armistice having been signed, it is incumbent on us, as founders of prosperity, with the sciences and the arts, to become one of the greatest upbuilding factors in the future, to help reconstruct that which has been torn down and destroyed by the ravages of war, and to promote new ideas for the world's future prosperity.

Emerging from the greatest war the world has ever known, not only in the number of men engaged and the use of the most deadly weapons, but in the destruction of property, what does this mean for the future? The employment of many engineers to reconstruct, and to rebuild in an improved form.

In the future the names of many of you engineers will be enrolled among those who have attained high public standing through great achievements. Many in our profession have thought, done, and suffered much in former days. Childhood may seem to be at almost an immeasurable distance in the past, but something that we have accomplished on account of its overpowering vastness seems near. It is like a beacon light, far away but seemingly near.

It is said, "The schoolhouse of the world—human experience—however expensive, has something to teach." Shall we learn our lesson readily?

Snowslides Removed by Sluicing

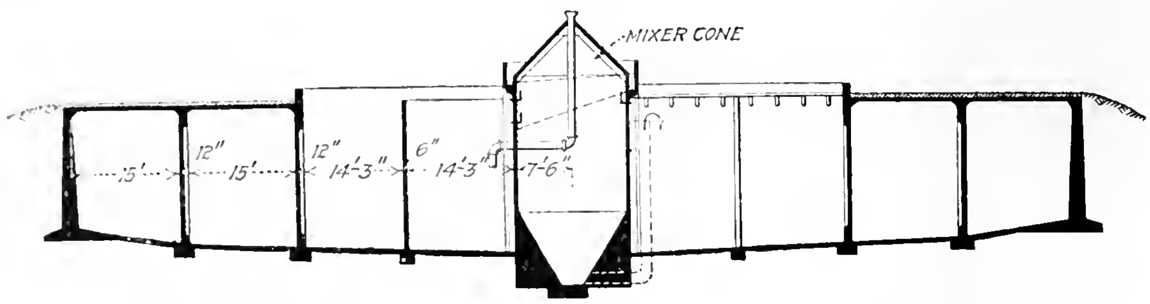
Three snowslides which blocked the line of the Government railroad in Alaska between Anchorage and Seward were to be removed by sluicing, according to the *Alaska Railroad Record*. One of the slides was 25 ft. deep over the track and the other two were 50 ft. in depth, the locations being at Mile 76½ and Mile 72, respectively. Nearby streams flowing only during the melting of snow in spring were available for removing blockades.

Combined Aërator and Mixer for Colloidal Water

Odor, Color, Taste and Turbidity in Underground Water From Cavernous Limestone Make Treatment Difficult

HIGH colloidal content and infrequent heavy turbidities are removed from the water-supply of Bloomington, Ind., by a combined aërator and mechanical mixer consisting of a conical concrete framework in which are embedded a series of short angles interrupting the flow.

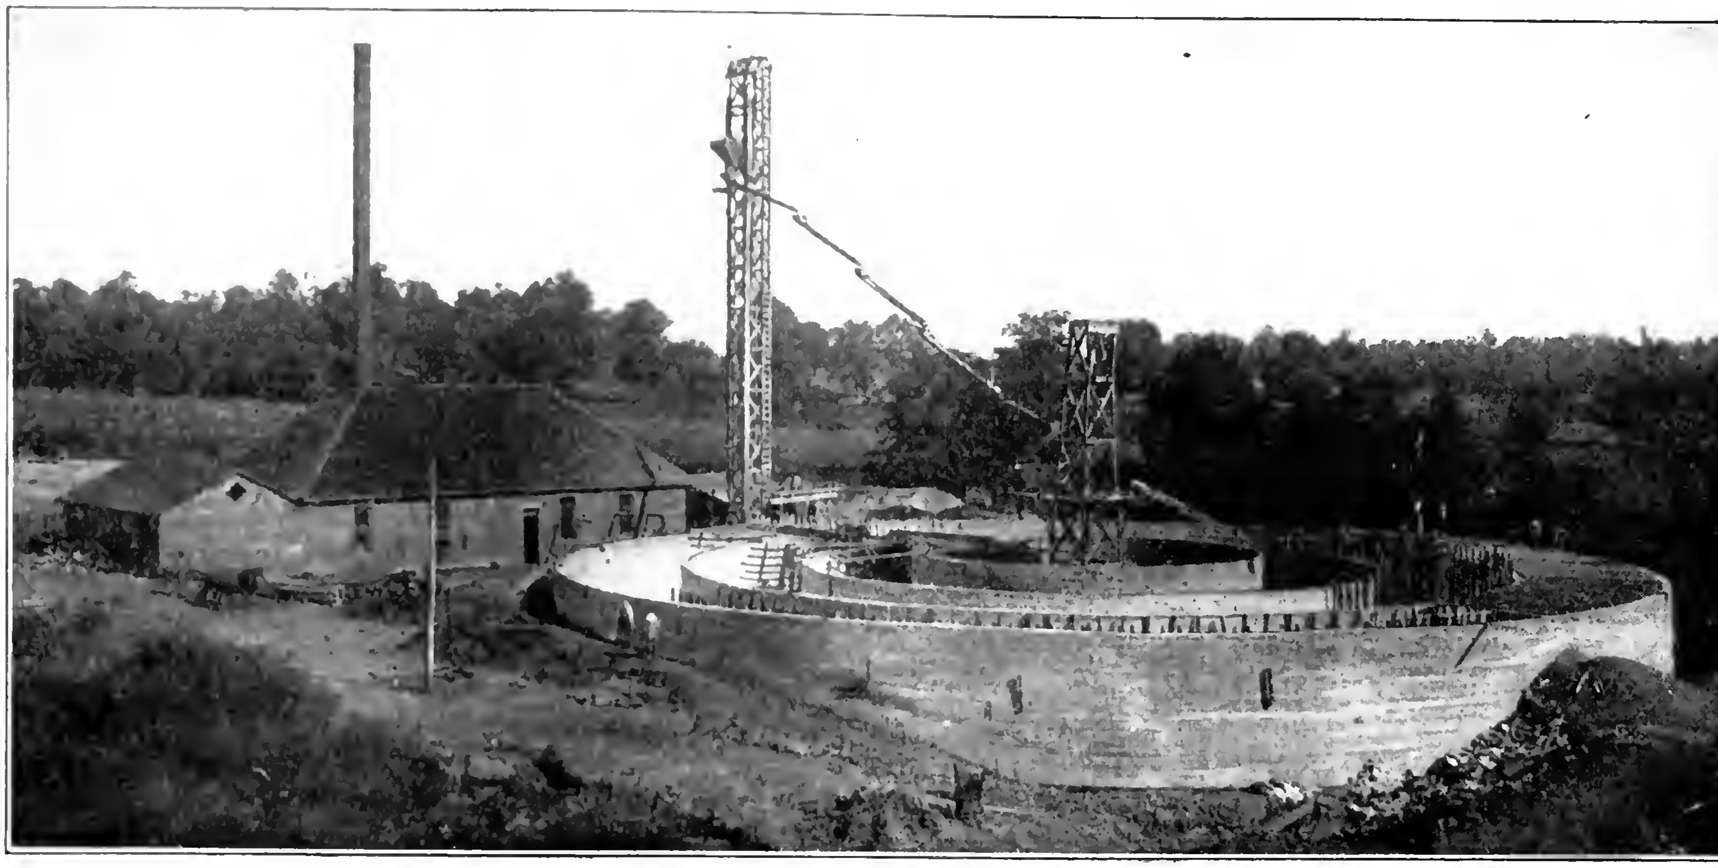
Geological conditions have made the water-supply problem particularly troublesome, the city being in the Mitchell limestone district, which is cavernous and underdrained to such an extent that deep rock wells are practically impossible, while the numerous fissures make the impounding of a sufficient supply difficult and uncertain. After numerous attempts to impound the water of several small streams in the vicinity, and after giving consideration to pumping water from White River, nine miles distant, a reservoir was constructed on a suitable site about three miles from the present pumping station. This reservoir is supplied entirely by springs and underground streams and has an approximate capacity of 1,500,000 gallons.



SECTION THROUGH BLOOMINGTON SETTLING RESERVOIR

The conditions in this reservoir, together with a high iron content in the water, favor the production of organic growths, which during certain seasons give objectionable odors and tastes. This feature, coupled with the fact that at times of extremely heavy rainfall the underground streams carry considerable turbidity, made it necessary to provide a purification system and means for the removal of the tastes and odors. Experiments showed that with complete aëration and the use of chlorine gas, followed by coagulation, a satisfactory effluent could be obtained. With the high colloidal matter and periodical heavy turbidities, it was considered advisable to provide not only the treatment just indicated but also to construct a specially designed sedimentation basin in connection with a small storage

CONE MIXER IN OPERATION



CIRCULAR BAFFLED RESERVOIR CONCRETED BY TOWER AND CHUTE

reservoir, having ample means, while in service, for removing settled solids. The combined reservoir and basin is of reinforced concrete, circular in form, 140 ft. in diameter, the outer ring, 30 ft. in width, being covered.

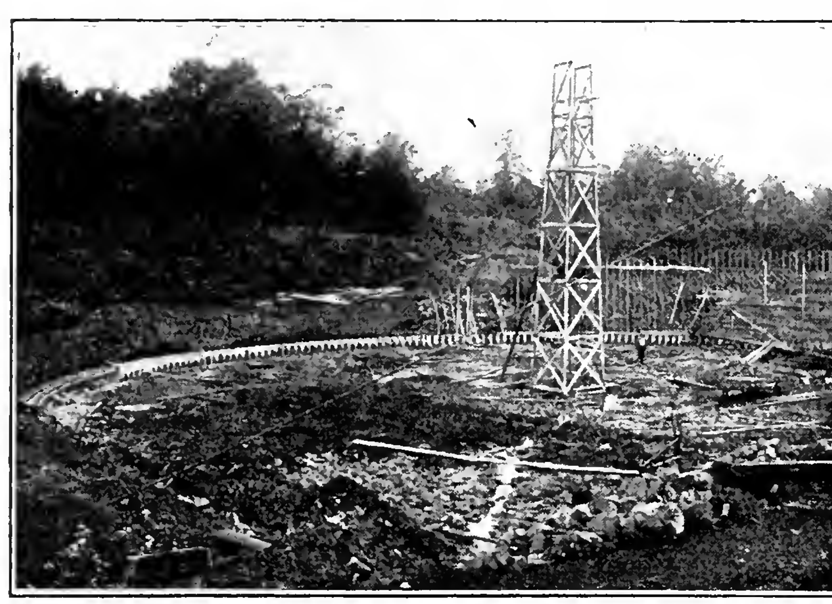
The combined aërator and mechanical mixing chamber is the special feature. The aërator, which is constructed of reinforced concrete, is formed in the roof of the circular mixing chamber. It is conical in shape, 16 ft. in diameter, and has a slope of 37½°. Water is discharged from a pipe rising just above the apex of the cone, and sprays down over the conical surface, in which are embedded a series of short angle irons which are set in such a way as to increase the splashing effect and to give the water a circular or spiral motion.

This additional length of travel not only gives a more complete mixing effect but considerably increases the contact period. The water falling over the edge of the conical surface flows into an inclined circular gutter or trough, to augment the circular motion as it passes into the water of the mixing chamber, which is located in the central compartment of the basin (see drawing). This arrangement, with the method of discharging the water from the chamber, creates a high velocity which gives a complete mechanical mixing of the coagulant, this being added in solution at the beginning of the operation. The contact period is from 16 to 24 min., depending upon the service demand. The water from the mixing chamber is delivered at or near the surface level in the second compartment, where a subsequent quick sedimentation is produced, due to complete distribution. Complete clarification takes place before the covered storage is reached. The chlorination treatment is provided for both before and after sedimentation and coagulation.

In the construction of the aërator, after the cone was cast and the angle irons were embedded in the concrete, the upper legs of the short angles were wrapped with wire and the entire surface was coated with a thin grout, to prevent oxidation and deterioration.

The cost of forms in the construction of the exterior reservoir wall was considerably reduced, and the placing of steel was facilitated, by the use of a series of concrete blocks that were cast in place radially and to an exact circle.

These blocks were entirely enveloped in the poured concrete and permitted the deposition of the concrete of the wall and footing section, which extended 2 ft. 4 in. outside and 6 ft. inside of the interior surface, at the same operation. Six per cent. of hydrated lime was added to the cement to increase plasticity in the depositing of the concrete for the outer wall. The usual tower method was used in placing the concrete, the mixture being chuted from the main tower to a central auxiliary tower from which continuous placing took place.



THIN CONCRETE FOOTING SLABS HOLD SUPPORT BARS AND FORMS

The entire work, including the pumping station at the lake and the transmission pipe line, was designed and constructed under the supervision of Charles H. Hurd, consulting engineer. R. J. Buck, of Mr. Hurd's staff, acted as resident engineer. D. E. Helfrich is superintendent of the plant.

Function of Corporate Contract Bonds—How Obtained

Great Care Must Be Exercised by Surety Companies in Issuing Them — Questions Asked by Bonding Companies — Many Rejections

By Harmon V. Swart
Specialist in Contract Bonds, New York City

A CONTRACT bond is a guarantee of the financial standing, moral integrity and practical ability of a contractor to perform the work which he contracts to do. It should, therefore, be seen easily that the many questions which the surety companies ask the contractor as to his standing are not idle. It is not a fact, as often stated, that any contractor can get bonds by paying the premium, but yearly large numbers are refused, and it is a mark of distinction to be able to procure one. With these facts in mind, an enumeration of the questions asked and the reasons therefor may aid in a better understanding of the time necessary to verify the contractor's answers, may induce him to make early application for his bond and so arrange his affairs that there will be no delays due to uncertainties as to his standing.

Years ago, during the early development of the contracting business, and before the days of such sizable contracts as a New York subway, a 2200-room hotel, a tunnel sewer running several miles, a cantonment, an industrial city, or a railroad tube under a great river, the contractor doing the work was not required to give a bond. The man who was having the work done knew the contractor personally, knew him to be honest and able to complete the work, and that was security enough. Later on, some sort of security was deemed necessary, and a personal bond was given by the contractor to guarantee that he would complete the work in the specified time and would do it according to the stipulations set forth in the specifications.

After experience proved that changes in the financial status of the contractor not infrequently made it difficult, if not impossible, to collect damages in the event of nonfulfillment of the contract, more dependable security for performance was found desirable. This brought into being companies organized under the banking and insurance laws, designed to furnish bonds for contractors to be given as a security or guarantee that their contracts would be performed in strict accordance with all agreements and stipulations. These bonds are called "corporate surety bonds"; they are commonly known as "corporate contract bonds."

Surety Company Assumes Real Responsibility

The companies themselves are known as bonding or surety companies and are required by the banking or insurance laws to carry and maintain unimpaired their capital and surplus, as well as a liquid reserve fund sufficient to pay any losses impending by reason of defaults of the contractors bonded. By issuing a contract bond, the surety company assumes a genuine responsibility, which makes it necessary for the surety to satisfy itself that the contractor is thoroughly reliable and abundantly able to execute the contract.

Because they overlook this necessity, many contractors, in obtaining their first bond, are inclined to feel that the surety company is entirely too inquisitive and too much inclined to ask questions intended to elicit information which, they feel, does not concern it and can have little or no bearing on the subject. The request for the information is neither idle nor foolishly inquisitive. Naturally, the underwriters, like all other busy men, care nothing about the financial standing and personal relations of any contractor, except in so far as this information is needed by them in judging whether or not he is a good or a hazardous risk. A dependable contractor, who has nothing in his record he needs to conceal, is perfectly willing to have his reputation and bank accounts thoroughly searched. Having been accepted after the rigid investigation that surety companies very properly make, he may well be proud that he is able to obtain contract bonds.

What the Surety Wants and Why

Surety companies ask from a contractor doing business as an individual sufficient pertinent information along certain lines to enable them to underwrite him; that is, to determine whether he is a proper man for whom they may, with reasonable safety, pledge their credit in the form of a bond to those with whom the contractor makes agreements. They ask the contractor how he has conducted his business in the past, in order to determine whether or not he takes advantage of every technicality in a contract and just keeps within its bounds and no more; or whether he is thoroughly conscientious and eager to do not only all the contract calls for, but possibly a little bit more, if necessary. They ask whether he has paid for material on note or invoice bases and whether he met payments promptly, because they want to know whether he is making wise use of his capital and borrowing capacity, or whether he is overreaching. The answer to this question has an obvious bearing on the question whether bonds should be issued for him. Financial embarrassment would be one of the first and surest causes of default on the part of the contractor.

The surety asks which type of subcontractors he employs, and the regard in which they hold him as a general contractor, in order to determine whether there is any likelihood of trouble arising between him and his subcontractors. It wants to know how he is regarded by architects, engineers and owners for whom he has done work, because such opinions afford valuable guidance, from an outside viewpoint, to his capacity and methods, both technical and business, and also to whether he is a man of his word, worthy of confidence and agreeable to deal with, or contentious, faultfinding and possessed of ability to deliver excuses rather than finished work. Similarly, the contractor's general reputation for honesty, integrity, reliability and dependability is inquired into. Why not? When you are asked to put your credit behind a man's promise to do something, it is natural to want to know something about the man who makes the promise.

Because the surety may become liable for the contractor's debts in case he defaults, it inquires as to his relations with banks on previous contracts; how his obligations were met; the line of credit that was extended by the bank and its inclinations as to future credit; as to his financial responsibility; cash in bank; whether he owns stocks and bonds and in which companies—whether old and established or new and unproved companies; as to any mortgages, and the property, and whether they are first or second mortgages. May the surety not also ask the contractor whether he

owns any real estate, and whether it is farm or city property, improved or not improved, income-producing or otherwise, free and clear of incumbrances and in his own name or in his wife's name? In some states the law prevents a wife from jeopardizing her property on behalf of her husband, so that property held in her name cannot well be considered an asset of the contractor.

Questions Regarding Equipment

After satisfying itself as to the character and financial responsibility of the contractor, the surety must also consider whether he is properly equipped to do the work and in a position to prosecute and expedite it. Hence, it asks full information as to plant and equipment and why it is suitable for the contract in question; the quantity of material on hand which is suitable for the contract in question; other contracts he has under way and their condition as regards completion; amounts of payments due and payable on work already under way, together with approximate due dates on future payments; whether any of these payments are assigned or tied up in any way by litigation, liens or differences of opinion. It needs particulars of each item.

For like reasons, it asks the amount of his loans from banks and other sources; the amount of accounts payable for materials and due to subcontractors for work under way or completed; a complete list of all other obligations, such as indorsements of notes, surety for others, etc.; whether the contractor has ever taken advantage of the bankruptcy laws; and, if so, it asks detailed information of the settlement with his creditors.

Is it not entirely natural and businesslike for one who is asked to assume financial responsibility for your debts to be interested in inquiries of this nature?

If the contractor is a corporation or a firm, the same lines of inquiry are pursued, also the assurance is required that each individual member of the corporation will back his company to the limit of his personal responsibility.

From this information a statement of assets and liabilities is made up, and, by a careful weighing of the value of the assets, a conservative net worth is shown. The balance of assets over liabilities must be real and based on sound assets in which slow assets and doubtful ones—such as equities in properties largely encumbered—are either disregarded or largely discounted. Apparent worth based on bookkeeping trial balances, until so analyzed and verified, carry little weight. The actual net worth is derived from real, available assets. Paper assets or slow assets that may have a financial value some day, if everything goes right and nothing untoward happens, receive little or no consideration.

Satisfied as to the contractor's financial responsibility, the board of underwriters then determines whether the contract on which a bond is sought is similar to the previous work handled by the contractor, or whether it is a line of work entirely or for the greater part new to him. Quite naturally, the surety company will issue a more substantial bond to a contractor doing familiar work, on which he has proved his ability, than on unfamiliar work where there is room to doubt his ability to handle it successfully.

For many years, contract bonds have been required on all municipal, county, state and Federal Government work, and it is fast becoming the custom to require the contractor to furnish a surety bond on private work of large volume. The latter condition seems to have created a misunderstanding on the part of some contractors, resulting in a mistaken belief that contract bonds are a necessary evil and are required only of contractors who are not financially and otherwise thoroughly reliable. As a matter of fact, a contract bond is a clean bill of health as to a contractor's financial and technical ability, his character, standing and record—a passport into the society of the elect. To be able to furnish such a bond is something of which the contractor has every reason to be extremely proud.

Moreover, the contractor who hesitates when asked to furnish a contract bond places himself immediately, and probably without realizing it, in the same category with the man who accepts as an insult any inquiry into his credit responsibility and refuses to buy, indulging the while the impulse of self-pity by fatuously declaring he will place his orders where his credit is good. Business and financial responsibility never shrinks from careful scrutiny, for the result of investigation is always additional good-will, an asset of the highest value. The contractor who fails to realize this is unwittingly doing himself a grave injustice; which, if inflicted by another, would be resented with no little zeal. A contract bond shows to the world that the acid test proves the contractor to be absolutely honest in action and intent as a man, thoroughly reliable and dependable as a contractor, and that he has the money to back up his reputation.

Contract Binds Owner Also

The contract bond also binds the owner, who is described in it as the obligee, to make payments at stated intervals in accordance with the terms of the contract, or run the risk of forfeiting the protection of the bond. The owner is ready and willing to carry out fully all his agreements, because the mere fact that the contractor is able to give bond is assurance that he has been looked up thoroughly, and his capability and responsibility have been verified from every possible angle—in short, he has been weighed in scales of minute accuracy and sensitiveness and found to be a plus unit, 100% pure.

There is still another point that should be cleared up in the minds of some contractors. No small number of them are not only under the impression that any contractor can get a bond by merely walking up and depositing the premium on the counter, but they fail utterly to take into consideration the element of time necessary to complete the transaction. I believe I have made it quite clear that every contractor cannot get a contract bond, but the realization that the matter cannot be unduly hurried is of equal importance.

From the kind of investigation made by surety companies and the reasons for it, given earlier in this article, it requires no great stretch of fancy to realize the importance that is placed on the answers made to inquiries; and, from the nature of the questions, it is equally easy to realize that a sufficient amount of time must be allowed to verify the information given. Here again the contractor suffers a self-inflicted injustice by not making application for the bond early enough, and thus lays himself open to the embarrass-

ment of having his application rejected. If contractors could be made to realize the large percentage of applications, from concerns of supposed good standing, that are rejected, they would allow more time for proper investigation, and fewer disappointments would result.

The best possible advice that can be given to the individual contractor is to "get his house in order," for in this period of reconstruction there will be an abundance of work for the man who is ready and able to take it.

The Engineer in Politics—By One Active Therein

W. A. Stinchcomb, Recent Candidate for Mayor of Cleveland, Explains Why Engineers Are Fitted for Solving Political Problems

ENGINEERS themselves are largely to blame for their present position and relatively inadequate compensation, according to W. A. Stinchcomb, county engineer of Cuyahoga County, Ohio, and recent candidate for mayor of Cleveland. In an address prepared for the recent meeting of the American Association of Engineers, reproduced below practically in full, he strongly advocates participation in politics both by the association as a body and by individual engineers. Even the problems of financing and taxation should be attacked by engineers, he asserts, because of their experience in the execution and organization of work on the basis of lowest unit costs, and engineers are urged to take a dominant part in civic life, not only as a right, but as a duty they owe to society. Mr. Stinchcomb said:

To say that the American Association of Engineers and its members shall not go into politics would be to deny to the country and the local communities within which the association has chapters the service of an organization of men who, by natural ability, by education, by training and by experience are most capable of serving the public and in directing and educating the voters on questions of public policy, and would deny to its members the fulfillment of their obligations as citizens of this republic.

Now, I know that a natural tendency exists among engineers not to take an active part in politics, but by this they evade their full responsibilities as citizens. Shall anyone say that the engineer's training and experience do not better fit him to solve the problems of government, as our civilization becomes more complex, than one trained in any of the other great professions?

Nature of Political Problems

In our cities practically all of our public problems are subject to scientific analysis. Is the subject one of developing the physical plan of the city, including the adequacy and location of its highways, the kind and strength of its pavements, the development of its parks and recreation facilities, the working out of proper drainage or the planning of its transportation facilities, either rail or water? Surely, the engineer is best qualified to solve such problems. He is now called on for advice in these matters, and in my opinion he should be the one to decide.

In matters of public health, as influenced by problems of sanitation such as sewage and garbage disposal, water-supply and building and housing regulations, he is best qualified. On questions affecting the control of public utilities such as transportation, electric or gas supply and telephone service, his engineering training best fits him to bargain with the trained mind representing the public-utility companies, and to know when the contract has been made that justice is done both public and service corporation.

As cities extend further into the realm of municipal ownership of these public utilities, the engineer's obligations to serve the public in an executive capacity increase.

Even in the welfare and social problems of the city his analytical training fits him to search out the cause of our social evils and ills, to relieve them rather than apply only palliative and preventive measures. Shall anyone say that he is less qualified to organize and direct the ordinary housekeeping affairs of a city because of his training and experience?

One of the most difficult and always present problems of all government is that of financing and taxation. It is the constant duty of the engineer in his practice so to design, execute and organize his work that in terms of unity cost that cost shall be as low as possible. All problems of public taxation must go back to a proper appraisal of the property taxed, whether that property be in a tangible or intangible form. Here again his experience and training fit him well to serve efficiently.

Our national government problems are best solved when the engineering mind influences their solution.

And so, in my opinion, the engineer should take a dominant part in politics, and this association as an organization should wield a forcible influence in determining the civic and governmental policies—not as a right only, but as an obligation which both the engineer and the association owe to society.

Political Activity Beneficial to the Association

"But," I hear some timid soul say, "what effect will that action have on the engineer and this assocation?" In my opinion, it cannot be anything but beneficial.

This convention has had its attention called to the inadequacy of the salaries paid engineers in public service. Various means will be discussed as to methods by which salaries may be properly and equitably increased. How better can this be done than by the members of this profession taking an active interest in the political questions of their communities?

We have noted the appointment of men fitted by neither education nor training to take charge of departments of public service which really require the services of the trained engineer. We have seen the engineer subordinated to such superiors. He has seemingly been content to let his "light shine under a bushel," and have the accomplishments of his brain and energy appropriated by those to whom they do not rightly belong. By a more active participation of the engineer in politics these injustices would be removed and credit would be bestowed where it rightfully belongs.

We have seen national organizations of other professions jealously guarding the business interests of the members of their professions. There is the national bar association and the various national organizations of the medical fraternity, whose efforts are used not only in maintaining a proper code of ethics in the profession, but in seeing that the members of that profession as a body are not discriminated against by the passage or operation of what they consider unjust laws. And so, in halls of legislatures their representatives are seen when measures affecting those professions are under discussion—and the professions referred to do not have to do with the public work of the state in any degree compared with the engineer.

It has always seemed to me that the engineer himself has been to blame for the position in which he is held by society and for the meagerness of the salaries paid by both public and private corporations for his services. He has been retiring in his nature, content in too large a degree to take his reward from the satisfaction growing out of difficult problems well solved and difficult work well performed.

We cannot in a democracy expect to maintain our Government for any length of time in advance of the intelligence of the voters. The intelligence of the voter is only expressed through the polls and is influenced by the kind of political education which the voter received. In elevating the standard of citizenship the engineer can and should be a leader in his community. To be anything less not only results generally to the disadvantage of the individual, but decidedly to the disadvantage of his profession, and is a direct evasion of the responsibilities of citizenship which his training and ability impose upon him.

ENGINEERING LITERATURE

A REVIEW OF BOOKS AND A LISTING OF NEW PUBLICATIONS

Railway Development

EFFICIENT RAILWAY OPERATION—By Henry S. Haines, M. Am. Soc. C. E., M. Am. Soc. M. E., Formerly Vice-President and General Manager of the Plant System of Railroad and Steamship Lines; Also Commissioner of the Southern States Freight Association; Ex-President of the American Railway Association. New York: The Macmillan Co. Cloth; 6 x 9 in.; pp. 709; illustrated. $4.

"Railway development" would seem a more appropriate title for this interesting book, since it deals only incidentally with railway operation—as this term is usually understood—but consists mainly of a summarized review of history and development and future prospects in the entire field of railway construction, equipment, organization and service.

Bridges, foundations, concrete, tunnels (ancient and modern), rails, track, signals, coal and water supply, freight yards, and passenger and freight stations, are covered in 100 pages. Locomotives, cars, brakes, couplers, car lighting and heating and various allied subjects occupy 100 pages. Traffic and transportation (100 pages) include accidents, train speed, train equipment, ticket and baggage methods, car interchange, tonnage rating, train resistance, dispatching and block system. Operation (34 pages) covers organization, personnel, engineering department and training for railway service.

Obviously, with such a wide and varied list of subjects in a limited space, the treatment touches mainly the high points and is necessarily incomplete in many respects. Some inaccuracies occur. For instance, the Belpaire boiler is attributed to France instead of to Belgium and is said to have radial stays, whereas its crown and top sheets are flat and the radial-stay boiler is an American type. Comparison of railway and water transportation is hardly illumined by the statement that a freight train "can" make the round trip from Buffalo to New York in five days while a barge "requires" six weeks. Probably the train does not make such trips, while the barge time includes waiting for a return cargo. Certainly, even a barge "can" make the trip in less than six weeks.

Special mention may be made of the 50-page chapter on military transportation, an unusual subject of direct interest at this time. It begins with the achievements of Xerxes the Persian, but gives considerable attention to the Civil War, modern foreign wars and the great war of 1914-1918. The material is somewhat disappointing in that it deals largely with specific events and operations and, although it gives a mass of miscellaneous information, it has comparatively little about principles, methods or systems of organization. In fact, this chapter, like many of the others, is suggestive or informative rather than instructive, although it is highly interesting.

One fundamental principle that is brought out is that while there should be close correlation between the military and the railway organizations, the latter should be in direct control of the transportation service between the points designated by the former. Where military officers are permitted to control train movements there is sure to be confusion and congestion. This has been proved in many instances, including our own very recent experiences. A more technical work on this subject would be of value to both military and railway authorities.

Electric traction appears to find little favor with the author, and he sees little prospect of extensive development for either main lines or interurban lines. Rather pessimistically, he seems to view the jitney motor car as a possible serious competitor of suburban lines, but a considerable part of his chapter on motive power deals with electric locomotives and service. Appendixes covering 165 pages include a variety of statistics, together with rail specifications, and lists of tunnels, yards and large terminals; also regulations for military railway organization. A bibliography, an index and lists of railways and persons mentioned cover 50 pages.

The above notice of this book is intended as explanatory of its scope and character rather than as a critical review. It is a pleasure to add that the book is written in an attractive and interesting manner, and that it includes a wealth of information that can hardly be indicated within the space here available. With the exception of some diagrams and rail sections there are no illustrations, but they are not needed and would add little to the value of the book.

Walker's Building Estimator's Book

THE BUILDING ESTIMATOR'S REFERENCE BOOK—By Frank R. Walker, Author of "Practical Cost Keeping for Contractors." Third Edition. Chicago, Ill.: Frank R. Walker Co. Leather; 5 x 7 in.; not consecutively paged. Illustrated. $10, including 12 monthly supplements.

The earlier editions of this work were reviewed in *Engineering Record* of Jan. 1, 1916, in *Engineering News* of Feb. 17, 1916, and *Engineering News-Record* of Sept. 20, 1917. Changes in the present edition consist of detail revisions to bring practice up to date. Furthermore, the author announces that hereafter there will be issued to purchasers of the book a monthly supplement, which will carry new unit prices as they develop during the reconstruction period. Assuming the user's ability to adjust other costs to his own problem, the book continues to be a valuable aid to the building estimator.

Highway Handbook Much Enlarged

HANDBOOK FOR HIGHWAY ENGINEERS: Containing Information Ordinarily Used in the Design and Construction of Rural Highways—By Wilson G. Harger, C.E., and Edmund A. Bonney, Supervising Engineer, N. Y. State Department of Highways. Third Edition. New York: McGraw-Hill Book Co. London: Hill Publishing Co., Ltd. Limp binding; 4 x 7 in.; pp. 986; illustrated. $4.

The first and second editions of this handbook were reviewed in *Engineering Record* of Sept. 28, 1912, and Sept. 2, 1916, and in *Engineering News* of Jan. 16, 1913, and Oct. 19, 1916, respectively. The present or third edition contains about 350 pages of new material. Chapters have been added on mountain sections for roads; earth, sand-clay and gravel roads; preliminary investigations; and photography, camp equipment, and camp

medicines. The subject of specifications has been much enlarged. In fact, additions have been made to practically all the chapters. Although the author still draws numerous examples and standards from practice in the New York State Highway Department, the criticism that the original book was too local in character has been largely removed by the addition of material taken from reliable sources of information from Maine to California and Alaska. An evident effort has been made to bring the book up to date and to cover all phases of design and construction.

Vital Statistics Made Easy

VITAL STATISTICS: An Introduction to the Science of Demography—By George Chandler Whipple, Professor of Sanitary Engineering in Harvard University Member of the Public Health Council, Massachusetts State Department of Health. New York John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Flexible Cover; 5 x 7 in.; pp. 517; illustrated. $4.

Designed primarily for public health students, this volume promises to be of wide usefulness to health officers and sanitary engineers as well as in the classroom. The theory and practice of vital statistics are clearly and interestingly presented, with many useful observations on statistical presentation and the use of graphical methods in general. Enumeration and registration of population, population forecasts, the calculation of death and other rates used in vital statistics, and the other phases of the subject are taken up. The discussion extends to expectancy tables and the law of probabilities. Apt citations, with historical and statistical data, are given. The use of thin paper, flexible covers and a medium-sized page places the volume among the handiest of the many almost indispensable handbooks of the day.

More Efficient Municipal Government

A NEW MUNICIPAL PROGRAM—Edited by Clinton Rogers Woodruff New York and London: D. Appleton & Co. Cloth; 5 x 8 in; pp. 392. $2.25.

EXPERTS IN CITY GOVERNMENT—By Edward A. Fitzpatrick, Ph.D., Director, Society for the Promotion of Training for Public Service. Editor, "The Public Servant." Natoinal Municipal League Series. New York and London: D. Appleton & Co. Cloth; 5 x 8 in.; pp. 363; illustrated. $2.25.

The present century has brought marked betterment in municipal government. In hundreds of cities the old, cumbersome system of checks and balances, with its divided responsibility, has given way to a simple form of centralized responsibility in which the value of trained permanent public servants is recognized. In over a hundred cities still more progress has been made through centralization of responsibility in a single executive officer and by a fuller recognition of the value of expert service. The first of the two volumes under consideration, "The New Municipal Program," is devoted to the principles of city government as embodied in the commission-manager plan. The second deals primarily with the need for experts in city administration, how to get them and how to keep them.

Each volume is a work of collaboration. The "Program" is the more concrete of the two, because it embodies and contains supporting arguments for a model city charter of the commission-manager type, something based on the experience of scores of cities during the past few years. The volume on "Experts in City Government" is, perforce, largely academic. It seems rather discursive—if not excursive into fields that are not very closely related.

Chapters in the "Program" that may be specifically mentioned are "Experts in Municipal Government," by A. L. Lowell, president of Harvard University; "Civil Service and Efficiency," by W. D. Foulke; "Franchise Policy," by Delos F. Wilcox, formerly with the New York Public Service Commission and later deputy commissioner of water-supply, New York City; and "City Planning," by M. N. Baker, associate editor of *Engineering News-Record.*

President Lowell, Mr. Foulke and Mr. Wilcox also contribute to the volume on "Experts," and there are also many other contributors, including M. L. Cooke, formerly director of public works of Philadelphia; Charles A. Beard, director of the New York Training School for Public Service, and W. H. Allen, director of the Institute for Public Service. These and other contributors deal with the subject of municipal experts from a variety of viewpoints.

Both volumes deserve the attention of engineers in or in close contact with municipal or other branches of Government service.

Against Government Ownership

GOVERNMENT OWNERSHIP OF PUBLIC UTILITIES IN the United States—By Leon Cammen, M.A., Associate Editor of the *Journal of the American Society of Mechanical Engineers;* Member, New York Academy of Sciences, Etc. New York: McDevitt-Wilson's. Cloth; 6 x 9 in.; pp. 142. $1.50.

Perhaps no gloomier view of what would happen to this country were government ownership of utilities to come has ever been written than is presented in this volume. All other industries, according to the author, would come under government ownership with or following utility ownership. Not merely democratic institutions, but their very spirit would give place to "an autocracy of central government." Our 48 states would become "simple electral [sic] districts." Our great corporations would be forced into politics by government ownership. There would be a reinforcement of "the sinister cohorts of enemy and Bolshevist propaganda." It is some comfort to learn that the author does not mean to imply that advocates of government ownership intend to bring all these evils on the country.

For the most part, the author confines his discussion to railways. He marshals many arguments against their being taken over by the Government. Most of them merit consideration, but some of them seem to be aimed at men of straw. Toward the end the author proposes a regional scheme of private ownership under Federal control. The book seems to be an honest and earnest attempt to save the country from the disaster which the author believes would result from government ownership—a condition that seems more remote than when the book was written a few months ago.

Pollution of Boundary Waters

POLLUTION OF BOUNDARY WATERS REFERENCE: Final Report of the International Joint Commission, Washington-Ottawa. Washington, D. C.: The Commission. Paper; 7 x 10 in.; pp. 56.

POLLUTION OF BOUNDARY WATERS: Report of the Consulting Sanitary Engineer upon Remedial Measures, Mar. 8, 1916. International Joint Commission. Washington, D. C.: The Commission. Paper; 9 x 12 in.; pp. 159; illustrated.

After six years of consideration, the joint commission created to consider the pollution of the boundary waters of Canada and the United States rendered its report last August. The report (summarized in *Engineering News-Record* of Oct. 10, 1918, p. 660), has just appeared in printed form. It is accompanied by a large supplementary report, dated Mar. 8, 1916, by Earle B.

Phelps, consulting sanitary engineer, giving the results of detailed engineering studies and estimates for sewage-treatment plants at communities on the Detroit and St. Clair Rivers, made under Mr. Phelps' direction by H. C. McRae, district engineer, and I. P. Kane, assistant engineer, and like studies for places on the Niagara River by F. C. Tolles, district engineer. The final report is notable for its conclusions that no untreated sewage should be discharged into boundary waters; that the claim of use of these waters for sewage dilution is well founded; and that where city water-supplies are concerned the degree of sewage treatment should be calculated so as not to overload water-treatment plants. A tentative standard is set up, based on recommendations made by the advisory engineers to the commission, George W. Fuller, Mr. Phelps, Prof. George C. Whipple, W. S. Lea, T. J. Lafrenière and F. A. Dallyn.

Canadian Electric Light and Power Plants

ELECTRIC GENERATION AND DISTRIBUTION IN CANADA—By Leo. G. Denis, B.Sc., E.E., Hydro-Electric Engineer, Canadian Commission of Conservation. Ottawa, Can.: The Commission. Paper; 7 x 10 in.; pp. 296; illustrated.

After a brief general summary, the electric supply of each city and town of Canada is described textually, the municipalities being arranged alphabetically by provinces. In addition, there are tabular summaries of power plants, transmission lines, consumption and rates, capacity, ownership, prime movers and generators, load, service, etc., and transmission lines and distribution. The textual descriptions of power plants give much information in small compass. The volume is a credit to all concerned in its preparation. A similar one for the United States would be welcome.

New Monthly Technical Journal Appears

Starting with May, a new technical journal, devoted to highway engineering and contracting, has appeared under the name of *Highway Engineer and Contractor*. It is published monthly (Chicago: International & Trade Press; $2 per year). The initial issue contains articles covering the general highway situation, highway design, highway contracts, selection of materials, maintenance, and cost of roads.

PUBLICATIONS RECEIVED

[So far as possible the name of each publisher of books or pamphlets listed in these columns is given in each entry. If the book or pamphlet is for sale and the price is known by the editor the price is stated in each entry. Where no price is given it does not necessarily follow that the book or pamphlet can be obtained without cost. Many, but not all, of the pamphlets, however, can be obtained without cost, at least by inclosing postage. Persons who are in doubt as to the means to be pursued to obtain copies of the publications listed in these columns should apply for information to the stated publisher, or, in case of books or papers privately printed, then to the author or other persons indicated.]

ANALYSIS OF STATICALLY INDETERMINATE STRUCTURES by the Slope Deflection Method—By W. M. Wilson, Assistant Professor of Civil Engineering, F. E. Richart, Instructor in Theoretical and Applied Mechanics, and Camillo Weiss, Instructor in Structural Engineering. University of Illinois. Urbana, Ill.: Engineering Experiment Station. Paper; 6 x 9 in.; pp. 218; illustrated.

LES APPLICATIONS DE LA PHYSIQUE PENDANT LA Guerre—Par H. Vigneron, Paris, France: Masson et Cie, Editeurs. Paper; 5 x 8 in.; pp. 322; illustrated. 7 fr. net.

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Value of Engineering in Public Life

Sir—It is evident that your effort to arouse the engineer to his full sense of civic responsibility is whole-hearted. It is equally evident that you have entire confidence in his ability properly to function in public life, and you are to be commended for the endeavor to inspire him with the necessary self-confidence to undertake his important position in relation to his fellow men.

But in your enthusiasm it seems that at times you become somewhat radical. As I read some of your editorials it would seem that the engineer by temperament and training is peculiarly and particularly fitted better to function under most circumstances than the man of any other profession.

Now, I am an engineer. I believe in engineers. And I am in full accord with your sincere efforts to raise the standards of the profession and to arouse in the engineer a full sense of his civic duty and full confidence in his own ability. But I cannot believe he would prove a cure-all for every ailment of our political, economic, or social structure, nor can I believe he would prove most efficient in every position of responsibility or in every circumstance. Engineers, like men of every other profession, have limitations. But I think that I understand your point of view in regard to this and other matters. *Engineering News-Record* is edited by engineers for engineers. It is, therefore, but natural that you should exhibit some professional prejudice, as I choose to term it. Also, it is undoubtedly necessary to be somewhat overenthusiastic upon a particular object in order to have the desired influence upon a class of men who are inclined to be overmodest and ultraconservative. I believe, however, that a tendency might in time prove to develop into a hobby.

ENGINEER.

West Webster, N. Y.

Engineering Training Fits Men for Various Opportunities

Sir—I have just completed reading your issue of May 29, 1919, and on p. 1075 note two interesting references to an article in a recent number written by a young man expressing his doubts of a future in the engineering field being sufficiently remunerative to warrant his preliminary effort and expense in fitting himself with a technical education.

May I voice a thought which comes from my personal experience and which seems to be universal among men with whom I have talked on the subject; namely, that a technical education as a foundation fits a man to any job of ordinary proportions and demands, makes him flexible to meet and qualify in the countless opportunities that come preliminary and preparatory to the great big opportunity that becomes that man's lifework.

Since graduating from college in 1909 I have suffered and enjoyed a varied experience, which in the main has been a commercializing of my technical training. I found in the early days of this experience that if I followed the field career my results would be mediocre and my end untimely, and with a view to the future looked about for some means of capitalizing my engineering education. I became a sales-engineer and trust that my present employers consider me such today. At any rate I am supervising a district sales organization whose effort is directed along the lines of sales-engineering service to the field—or, better still, engineering-sales service, for the advisory engineering service comes first in all cases. The men in this organization are, with a few exceptions, technically and practically trained engineers, and I am frank to say receive a monthly stipend considerably in excess of the $160 obtained by Lucien Alter as a laborer. These men are all in the early and middle thirties, with families of varying dimensions, and I know of two that receive flattering dividend checks from investments made on past surplus bank accounts.

There are vast opportunities for the technically trained man, and I sincerely hope that Mr. Alter will read this article and if any further inspiration is needed will be glad to give him some personal history by correspondence.

WILLIAM S. MILLER,
District Manager, the Lakewood Engineering Company, Cleveland Branch Office.

Cleveland, Ohio.

Salary Schedule Proposed for Railway Engineers and Draftsmen

Sir—In view of the considerable discussion concerning economic and social phases of the life of engineers and draftsmen and the attempts to better the situation generally, it may be of interest to state that representatives of the International Federation of Engineers' and Draftsmen's Unions received a hearing at Washington by the Board of Railroad Wages and Working Conditions of the United States Railroad Administration, May 12-13. In behalf of engineering and architectural employees in all branches of railroad service, both in field and office, a brief was presented to the board, and testimony was given concerning its subject matter. This brief embodied four principal suggestions considered to be of prime importance, and requested their adoption by the board in recommendations to the Director General of Railroads.

One of these was the request that in case the widely rumored reduction of forces should occur (it *has* already begun) a system of pro-rata furloughs should be instituted, to affect all employees who are classed as permanent; making it possible for many men to tide over emergency periods and for some to use their off time to find permanent locations elsewhere. These latter would naturally be taken from the rolls and thus automatically reduce the pro-rata lay-off for the remainder. When this method was suggested in our organization for the shipyard draftsmen, it was approved by them almost without exception as being preferable either to flat discharge or practically enforced acceptance of lower ratings.

A further request was for the establishment of regulatory committees, to be composed of the more responsible technical supervisors and representatives of the managing officials. Such committees, by applying the schedule and budget principle to work which is to cover

somewhat lengthy periods, could greatly reduce the tendency of railroad work to go by fits and starts, and be of great value in breaking the disrupting force of periods of financial depression. The fact that projected railroad construction and the men at work on it usually feel the first effects in times of stringency hardly needs repeating, but the fact of continual danger in breaking up field and office organizations and throwing the men into the market, to compete against and undercut those left at work anywhere in the country, warrants frequent repetition.

Any abrupt and continued cessation of plan-making by engineers and architects is bound to have results reaching far out into labor and business fields.

The third point of the brief was the creation of office committees, similar to those in many industries, which will put into operation the classification of technical employees and the standardization of their positions, so far as these objects may be accomplished. It was suggested that machinery be adopted for this purpose similar to that instituted by the Macy board in the private and Government shipyards. In this way matters of classification and the adjustment of differences are taken up with supervisors and department heads or managing officials, and in rare cases, of special difficulty, with a regional examiner appointed by the board.

And, finally, there was presented the following salary schedule which we feel is very moderate and which is a minimum scale of monthly pay:

Chief draftsman	$300.00
Leading draftsman or squad-man	250.00
Draftsman, Class A	210.00
Draftsman, Class B	175.00
Draftsman, Class C	135.00
Tracer, Class A	125.00
Tracer, Class B	75.00
Assistant engineer (or engineer-inspector)	250.00
Assistant inspector, Class A	200.00
Assistant inspector, Class B	150.00
Instrumentman	210.00
Rodman, Class A	175.00
Rodman, Class B	150.00
Tapeman, Class A	125.00
Tapeman, Class B	100.00

Regular hours to be 7½ hours on five days of the week and four hours on Saturday, making 41½ hours per week; no overtime except where absolutely necessary, and at the option of the employees, and time and one-half for all overtime ordered or made necessary. All traveling and other expenses incurred for railroad business, and also expenses attached to moving headquarters, should be allowed. Civil service rules should apply regarding vacation, holiday and sick leaves. No salaries now in existence are to be reduced. This schedule is slightly lower than that of the Macy board award to marine draftsmen, and it is certainly small when compared with the more than 100% increase in living costs in the past five years.

The publication of the full record of this hearing, and also of a previous hearing of representatives of the American Association of Engineers, is contemplated by the International Federation of Engineers' and Draftsmen's Unions. It may be news to many of your readers that 28 locals were represented in the convention of our international in New York on Apr. 1. The president and secretary, respectively, of this federation are A. J. Oliver and A. H. Miller; the address of the latter is American Federation of Labor Building, Washington, D. C.

T. S. FORD,
Chairman, Publicity Committee, Draftsmen's and Designers' Union, Local 14.
Chicago.

Are Services Paid What They Are Worth?

Sir—I was surprised and just a little shocked to note the attitude expressed in the letter written by the president of the Rensselaer Polytechnic Institute, as printed in your issue of May 29, 1919, p. 1075. I certainly wish to take issue with his statement that "services, in the long run, receive the payment that they are worth." An advertisement in the *Literary Digest*, in its appeal for increased salaries for school teachers, but which holds good for engineers as well, contains the following:

> The men and women who are making the Americans of tomorrow are being treated with less consideration than the janitors who sweep out the buildings in which they are employed; they are earning on the average less than the wages given to scrubwomen employed in the public buildings of the United States Government. Normal-school graduates receive less salary than street sweepers; high-school principals and superintendents less than section foremen; country school teachers less for instructing the farmers' children than he pays his hired man to feed the hogs.
>
> In a certain town of Illinois, for instance, the average wage of 15 miners for one month was $217, while the average monthly salary of 15 teachers in the same town was $55. In another town a miner—who, by the way, was an enemy alien—drew more than $2700 last year, while the salary of the high school principal in the same town was $765. We welcome with all our hearts the long-belated recognition that is being given to the man who works with his hands. We believe that this same workingman will be the first to join with us in asking better pay for those who teach his children.

Unless the teachers of this country are not worth a living wage it would appear that Palmer C. Ricketts is clearly mistaken when he states that "services, in the long run, receive the payment that they are worth." That remark belongs to the class of commonly accepted generalities usually found, upon analysis, to have so many exceptions as to bear little relation to the facts. The basic idea that services should be paid what they are worth is far from being universally accepted as a general principle.

Bear in mind that $1500 per year provides bare subsistence at present-day prices for an average family of five, and that $2100 is required to maintain "security and citizenship level," according to a recent Federal wage inquiry. What does the average salary of thousands of ordinary engineers look like? Not members of the American Society, or presidents, managers, and chief engineers of corporations, but just average engineers?

Consider these instances: Railroad engineer, 13 years' experience, in charge of construction, $135 per month; four assistant engineers have salaries ranging from $96 to $124 per month, and from 3 to 17 years' experience. *On the same job*: Steam-shovel engineers, $200 per month; contractors' chief clerk, $150; team foreman, $150; fireman, $125.

On another job an assistant engineer, a graduate of exceptional ability, supervising the activities of several squads of survey parties, received $35 per week. One of his rodmen, 18 years of age, earning $20 per week, was given the job of carpenter foreman at $65 per week, *although totally inexperienced!* The chief engineer on this several million dollar construction job received $75 per week.

If engineers are being paid all that they are worth, and this amounts, as it does in so many instances, to less than is required to live decently, there should be only one of two courses open: Either teach engineers to earn more, or else get along without them.

I believe that most men who are in engineering are in the game because they love it. They have no longings for "royal salaries," and are really willing to devote their lives to service to humanity, but, first of all, they have to live to do it. How can engineers make progress when they cannot afford to buy the books and magazines which are necessary? What sort of work can we expect from the engineer with righteous discontent in his heart because he knows his family is suffering hardships while others producing much less receive a great deal more? Certainly, the engineer deserves a little more than the average mechanic or common laborer, if only because of the extra expenses due to societies and studies that will enable him to learn better methods and thus render higher and better service beneficial to all mankind.

Until our intellectual leaders become sufficiently progressive to advocate methods making for social justice, and a fair opportunity for everyone, there will always be a fertile ground in which Bolshevism or some similar symptom of economic protest may develop. America is far from being free from the taint of it.

The only positive remedy is *more production, more equitable distribution*, and the *elimination of unemployment*. The time and motion study of the industrial engineer, the social economist, the welfare worker, big business, labor, all thinking men, can, through intelligent coöperation, achieve in the short period of ten years any reasonable economic ideals. The misfortune is that our intellectual leaders dismiss such thoughts as these with the epithet of "paternalism," and our radicals cry that they are opposed to the spirit of democracy, or anarchy, or socialism, or unionism, or whatever cause they may happen to espouse, while misery, disease, and poverty remain at liberty to choose their victims.

E. N. GOLDSTINE,
Junior Member, Am. Soc. C. E.

Terre Haute, Ind.

Sir—In your issue of May 29, 1919, p. 1075, you print two letters commenting on a letter to you signed by one Lucien Alter. I feel somewhat presumptuous in taking issue with either the president of Rensselaer Polytechnic Institute or a man like Mr. Stierlin with his long years of experience. I shall have at them both, however, for I believe that both, while they sense in a vague way the undercurrent of unrest which is disturbing our profession, have either missed entirely or deliberately ignored the conditions which are causing it.

First, Mr. Ricketts: I feel sure that when one takes into consideration the dollars actually spent and the dollars a man could have earned if employed productively during the time he was busy at college, one would not be far from the truth in setting the expense of a college education at \$1500 a year.

The engineering education does not pay in money. It is an intangible something that seems to be part and parcel of the profession, a hope for the future and a certain measure of the idealism and professional pride which keep us in engineering work. This is particularly true of the young man—not the graduate of a year or two, but the man from five to ten years out of school.

What is a fair wage for such a man? Certainly, he has a right to expect to be able to support his wife and children decently. There are those who dare as far as a wife, but I maintain that the thought of possible children is a nightmare to most young engineers of my acquaintance.

Now, Mr. Stierlin: This gentleman writes of the very things I mentioned above. The idealism keeps us at our work, but it is the despised dollar that pays the butcher and baker—the fellow citizen for whom we are to create useful things. We aim not at an estate to leave behind us, but at a chance to live a full life cleanly and honestly, to pay our bills and look every man in the eye.

I feel certain that these gentlemen have written hastily. Do they know that local engineering clubs and societies the country over are affiliating with the American Federation of Labor? If they know that, do they realize what that means to our future professional life? Has either of them really endeavored to get first-hand information of social and economic conditions in the profession outside of the little section that comes under his personal observation?

I would commend to them the American Association of Engineers, which is spending time and money to seek out and cure the ills we suffer from as a profession. Knowledge of them may be had for the asking. The discontent is widespread and not at all confined to surveyors and draftsmen; even if it were, they are our engineers of tomorrow.

Let us not disagree among ourselves; that way lie confusion and defeat. Let us rather find the right solution by careful investigation, and then work together to bring about the better days. ERNEST R. TAYLOR.

Cleveland, Ohio.

Sir—It is evident from a letter appearing in your issue of May 29, 1919, p. 1075, that Palmer C. Ricketts, president of Rensselaer Polytechnic Institute, is greatly concerned over the effects that discussions relative to the compensation received by engineers, lately appearing in your journal, might have upon prospective students of the profession. This letter refers to a previous one published in your issue of May 8, 1919, p. 931, which is worthy of closer reading than that apparently given it by President Ricketts. In this connection, I desire to point out that young Alter did not state that he intended to spend \$1500 a year to obtain an engineering training, but spoke about an investment of \$1500 per annum, an entirely different matter.

I happened to be in Dayton last summer and came in frequent contact with young Alter, and it was I who gave him the estimate of the investment necessary to obtain an engineering education. After consultation of the catalogs of a great number of engineering schools, it was found that the average cost of one year's training would amount to about \$1000. To this was added \$500, the savings of a section hand for a period of ten months, at \$4 per day, thus making a total investment of \$1500 per annum. This figure (\$1000) agrees very closely with an estimate given by a member of the American Society of Civil Engineers in *Engineering News-Record* of Jan. 23, 1919, p. 201, and it is quite proper, in figuring the total investment in one year's education, to add to the amount that would actually be spent the amount that could have been saved had the student been engaged in manual labor.

President Ricketts also states that "the complaining letters are most frequently written by surveyors and draftsmen," but I find, in going over the files of *Engi-*

neering News-Record since Jan. 1, 1919, letters pertaining to the compensation received by engineers from the following: A member of the Am. Soc. C. E., a consulting engineer, a dean of an engineering college, a chief city engineer, a European student doing post graduate work in America; an employer of engineers; and a senior civil engineer in the Bureau of Valuation. In fact, only a few letters were written by draftsmen, and those pertained to the dispute with the Navy Department.

It is true that a young engineer is self-supporting from the start and through hard work "need not let the laborer pass him in the running." The remarkable thing is not that the engineer can hold his own and in the end pass the laborer, but that the laborer gives the engineer so good a race. It is almost unbelievable that the compensation paid for following the greatest of all professions is comparable with that received by a section hand.

In his comparison of engineering with the other professions, Professor Ricketts fails to see that while a doctor, dentist or lawyer can look forward to the time when he will have a practice of his own, over 90% of the engineering profession are forever doomed to work for someone else, by the inherent relation of the engineer to industry. That those at the bottom of the profession receive all they are worth is a subject open to much controversy; and that those at the top receive large compensation is not always true, unless they happen to be part owners of large corporations, in which case their large incomes are not the results of professional services rendered, but are the profits of business men. But what about the great bulk of the engineering profession who neither are at the very bottom nor yet have reached the top? What about the great multitude of assistant engineers, chief draftsmen, designers, detailers and checkers?

That a laborer remains a laborer is generally true, but that faithful service and hard work are invariably rewarded by adequate compensation is by no means the rule of the engineering trade. If it were, why should we see such phenomenal growth of an organization such as the American Association of Engineers, composed of men who rank from chief engineer down to the most humble draftsman, or the spectacle of those distinguished engineers and scientists employed by the Bureau of Standards affiliating with the American Federation of Labor, under the leadership of Dr. Edward B. Rosa? From my own experience, I know of assistant engineers employed by the Pennsylvania system, who were only earning $150 per month after 14 years of faithful service, while first assistants on the engineering corps were receiving $85 or perhaps $90 after 10 years. I worked under a chief draftsman of the bridge department of a large transcontinental line who only received $150 per month, and under another who was a graduate of a famous European university, and who after 12 years' bridge-engineering experience in America was getting the miserable pittance of $125 per month! Surely, these men are not mere draftsmen.

Engineering is essentially a question of service, and the engineer is, above all, an idealist. He is not in the profession for what he can get out of the world for himself, but for what he can put into it for others. However, this is no reason why he should be expected to support a wife and raise a family on $175 per month, which I find to be the average pay of the average engineering position. Surely, if the chief engineer of the Bureau of Public Roads can give up a big position to accept a smaller one for $1000 more a year, a prospective engineer has a right to inquire into the monetary remuneration he might receive from his profession, without being classed as a materialist. That engineering does not pay in the monetary sense, at least at the present time, is a fact to be attested by the sad experience of many. I do not wish to entice a youngster into the study of engineering under the pretext that it is a remunerative profession. Let him enter with his eyes open and realize that engineering is a "service that sweats for glory, not for meed." EDMUND FELDMAN.

Jefferson City, Mo.

Sir—Palmer C. Ricketts, in your issue of May 29, 1919, p. 1075, has answered the "invidious remarks" made by a young man concerning the opportunities for making money offered in engineering. He thinks that similar comments which have appeared in *Engineering News-Record* may have a serious effect on young readers who contemplate becoming engineers, and he makes a very positive assertion that an engineering education "pays in money if in no other way."

The trouble is that it usually pays in some *other* way. To illustrate this point we have Mr. Stierlin's letter on the same page with Mr. Ricketts', assuring us that to the real engineer the creation of things useful to mankind is compensation enough in itself, irrespective of worldly prosperity.

Historians or psychologists should make an investigation to discover who it was, or what it is, that is responsible for this suicidal conceit of the engineering profession. Others besides engineers create things useful to mankind, but few donate their services to society, or allow any discount for a laudable satisfaction to themselves from work well done.

Very little experience is required to disclose the fact that subordinate positions in engineering do not entail work so congenial, interesting and agreeable as to compensate for relatively inadequate salaries. It is precisely the pay for subordinate positions, drafting and surveying included, which has given rise to complaint. To what extent the promise of future highly remunerative positions can be considered compensation is a question deserving careful consideration. Some employers deliberately overemphasize this subject of future reward, but this despicable practice is by no means confined to engineering.

At least three factors should be considered before a proper appraisal can be made of Mr. Ricketts' remark that if a man "is able and continues to work very hard he is sure to rise in his profession and be well paid." How little pay can he afford to begin with? How long can he afford to make his apprenticeship? How certain can he be that his industry and ability will finally receive proper recognition?

Mr. Ricketts says, "the cold fact remains, that services in the long run receive the payment they are worth." If this means that all occupations are paid equitably in proportion to the effort involved, or the importance to the community, he is the first to announce that such an ideal state of society has been achieved. Mr. Ricketts does not mean this, and he does not mean that engineers' services (except young graduates') *now* receive the pay-

ment they are worth, or he would probably say so. What he does mean is not at once apparent.

Engineering News-Record has performed no greater service during the past few years than it has rendered by presenting to its readers a free discussion of this question of compensation for the rank and file of engineers. The law of supply and demand may "take care" of the common surveyor's pay and the pay of the ordinary draftsman, but the supply of young men whose ignorance of the situation with regard to engineering salaries is their best excuse for choosing this profession will certainly diminish when true conditions are understood.

It is unfortunate that in his letter Mr. Alter (he of the "invidious remarks") does not more clearly define the issue. He makes it seem that he is discussing the choice of becoming an unskilled laborer or an engineer, and Mr. Ricketts is led to remark that "the laborer generally has to remain a laborer," and has evidently taken it for granted that this is the only question involved. The real issue, for Mr. Alter and for most other young men who would contemplate becoming engineers, is not such a choice as this, which would easily be made. Properly interpreted, Mr. Alter's letter asks this question: If professional engineers after seven or eight years' apprenticeship (including four years in college) are not paid as much as common laborers, would common sense not indicate that it is wiser to choose some other profession, or some other line of business? There are others besides Mr. Alter who are asking this question.

JEROME FEE,
Assistant Engineer, Bay Cities Water Company
Coyote, Calif.

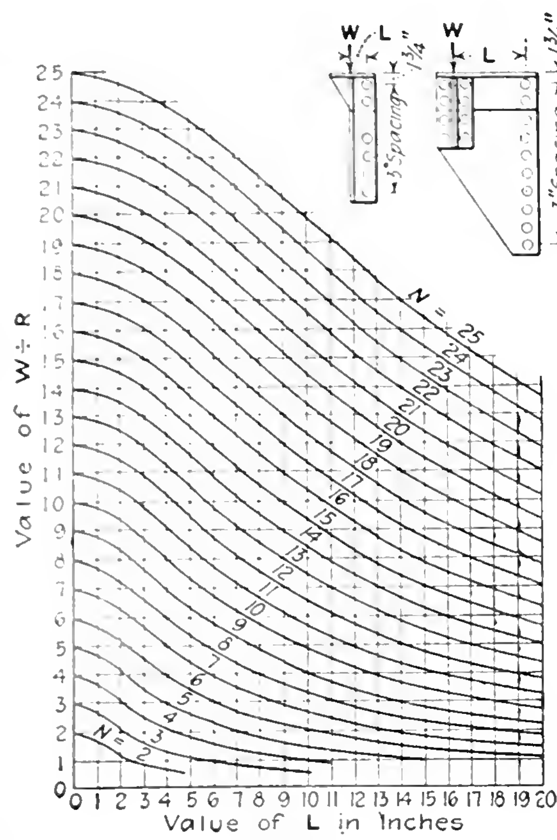

FIG. 1

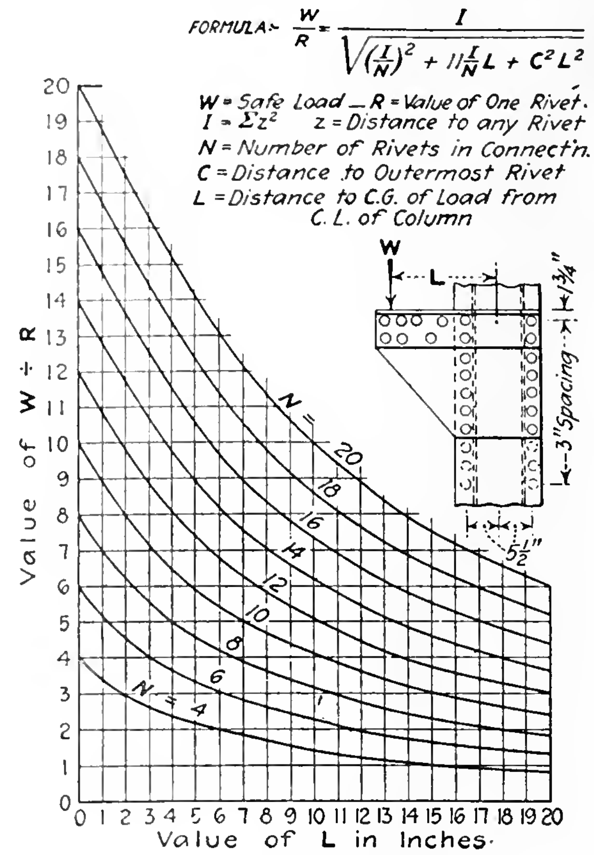

FIG. 2

DIAGRAMS FOR FINDING SAFE ECCENTRIC LOADS ON GUSSETS

Diagrams for Safe Bracket Loads

Sir—The accompanying diagrams for the safe load on gussets or brackets connected with one or two lines of rivets with 3-in. spacing have saved a lot of time and computation in our office. The method of using is probably self-evident. For spacing other than 3-in. the safe load is approximately proportional to the spacing, and for connections with a double line of rivets, where the distance between the center lines is between 10 and 12 in., the safe load is practically the same as for the 11-in. spacing given.

As an example, consider a two-line rivet connection as in Fig. 2, with 14 rivets of ⅞-in. diameter. To find the safe load W at a distance L of 8 in. from the center line: Find intersection of curve $N = 14$ with the vertical line 8 and trace horizontally to $W/R = 7$. Then, since the value of one rivet $R = 4400$ lb., the safe load $W = 7 \times 4400 = 30{,}800$ pounds.

Similarly, to find the size of the gusset connection required to carry a load of 25,000 lb. at 12 in. from center of column, using ⅞-in. rivets: $R = 6000$, and $W/R = 25{,}000/6000 = 4.17$; then, in Fig. 2, find 4.17 on left-hand scale, follow longitudinally to the vertical line for $L = 12$, and the intersection lies just below the curve $N = 12$. Hence a 12-rivet gusset is required.

The single-line rivet diagram, Fig. 1, is used in precisely the same manner.

Chicago, Ill. F. W. SEIDENSTICKER.

Water Hammer in Penstocks as Affecting Economy of Design

Sir—It seems to the writer that the penstock designer should specify the time of closing, T, before asking for bids on turbines or valves, rather than run the risk of a manufacturer's limit of T causing the use of tons of extra steel in the penstock. The designer can readily do this, since all the quantities except T in the following formula must be known even in a preliminary hydro-electric investigation. The term a, the velocity of vibration along the penstock, may accurately enough be taken at 2600 ft. per second, while h should be taken as a certain percentage of the maximum static head in feet, depending on the good judgment of the designer for its value. We have

$$T = \frac{\frac{LV}{h} + \frac{gL}{a}}{g} \text{ or approximately } T = \frac{L}{g}\left(\frac{V}{h} + 0.012\right)$$

in which

T = Time of closing of gate, in seconds.
L = Length of penstock, in feet.
V = Velocity of water in penstock, in feet per second, corresponding to Q. (Q is discharge in cubic feet per second before gate starts to close.)
h = Head due to water-hammer alone (in excess of static head) in feet.
g = Acceleration of gravity = 32.2 ft. per second.
a = Velocity of vibration along penstock, in feet per second.

The foregoing formula was obtained by solving for T in the equation $h = \frac{LV}{g\,(T - \frac{L}{a})}$ for ordinary water-hammer (T greater than $\frac{2L}{a}$), derived by Minton M. Warren in the "Transactions" of the American Society of Civil Engineers for 1915.

The justification for assuming the velocity of vibration equal to 2600 ft. per second and for thus making $g/a = 0.012$ in the above formula is that the value of T is not appreciably affected by even a few hundred feet or error in the value of a. V/h is readily determined with accuracy and since, in ordinary penstocks, it is several times greater than g/a, there is little use of wasting time in the computation of a value for a, at least during preliminary work.

However, unless a fairly accurate value of T is obtained by using the above formula, any preliminary estimate of the cost of a penstock may be greatly in error since, when T is less than $2L/a$, or when the closing is instantaneous, the stress due to water-hammer may become several times that due to the maximum static head.

It is customary to look into the most important things even in preliminary work, and the writer is inclined to believe that little attention is paid to the value of T until too late in the progress of many hydro-electric investigations.

Elmhurst, L. I. AUSTIN H. REEVES.

[Comments on Mr. Reeves' letter by Robert E. Horton, consulting engineer, and on both letters by Allan V. Garratt, of the Lombard Governor Co., follow.—EDITOR.]

Sir—There seems to me to be much more to the determination of the proper time of gate closing for turbines than appears from Mr. Reeves' letter. Considerations of economy of penstock construction do not wholly govern the time. The suddenness of load changes, the amount of fly-wheel effort in the rotating parts, the use or nonuse of surge tanks or pressure relief valves, and the allowable percentage of speed variation, must be taken into account in fixing the time of gate operation.

Albany, N. Y. ROBERT E. HORTON.

Sir—1. I have read with much interest the letters from Austin H. Reeves and Robert E. Horton.

2. The transposition of Minton M. Warren's formula, as suggested by Mr. Reeves, is interesting. It is in a little different form from that often employed by the present writer, which is

$$T = \frac{L\,V}{h\,g} + \frac{L}{a}; \qquad \text{(a)}$$

or, again, I sometimes write

$$T = V\left(\frac{L}{h\,g}\right) + \frac{L}{a}, \qquad \text{(b)}$$

which is very convenient for slide-rule work where you are chasing permissible values of V.

3. Mr. Reeves states that h "should be taken as a percentage of the maximum head." Has he not, in this, conveyed a different impression from what he intended, which may mislead some? If the static head is 50 ft., and it is intended that the pressure wave head shall be 100% of the static head, it must be used in Mr. Reeves' formula as 50, not 100.

4. Mr. Reeves' thesis, if I understand it aright, is that the designer of a penstock shall arbitrarily assume a value of h "depending upon his good judgment for its value," and then solve for T, and let it go at that, designing the thickness of the walls of the penstock on a convenient value of V and the sum of the static head which obtains and the value of h which he assumes on "his good judgment." It would seem that the above method leaves out of consideration some matters which will loom large when it comes to operating the plant; and the present writer is inclined to lean toward the opinion expressed by Mr. Horton that "the value of T cannot be determined from considerations of economy of penstock construction."

5. Perhaps the present writer's viewpoint may be made more clear by discussing an actual example: Let us assume a penstock 1000 ft. long, 10 ft. in diameter, with the water moving at a maximum velocity of 10 ft. per second, and with a static head of 50 feet.

6. By Mr. Reeves' method we should calculate the time, in seconds, less than which the water column should not be stopped, as follows:

$$T = \frac{\frac{1000 \times 10}{50} + \frac{32.2 \times 1000}{2600}}{32.2} = 6.6 \text{ seconds.} \qquad \text{(c)}$$

7. But, how about this 6.6 sec.? If the penstock is designed on that basis it is evident that the water-wheel gates must not be closed in a shorter interval of time. Now, with the full power that may be developed by this water column—which will be discussed later—it will be impossible to obtain a speed regulation, under commercial conditions, which will be tolerated by the electrical engineers of the plant, unless so large a fly-wheel effect is installed as to be very costly on a horizontal unit, and not only very costly, but also almost impossible to install, on a vertical unit.

8. Moreover, it should be remembered that there is absolutely no way of insuring that T may not be very much less than 6.6 sec. Some turbine gates are of such design that if liberated from control they will slam shut in a surprisingly short time. The critical time of a penstock, or that period of time of arresting the water column at which, or below which, the maximum pressure wave will occur is

$$T = \frac{2L}{a}; \text{ in our example, } \frac{2 \times 1000}{2600} = .769 \text{ second,} \qquad \text{(d)}$$

and the maximum pressure wave (for a rigid penstock) is

$$h = \frac{a\,V}{g}, \text{ or in our example, } \frac{2600 \times 10}{32.2} = 0.807 \text{ ft. head.} \qquad \text{(e)}$$

In practice it would be something less than that, depending upon the thickness and elasticity of the penstock walls, but the point I wish to make is that in our example the total head on the penstock, if the water-wheel gates slammed shut in 0.769 sec. or less, would approach 50 ft. static head plus 807 ft. wave-pressure head, a total of approximately 857 feet-head.

9. The supposition in the previous paragraph is by no means chimerical or fantastic. Just such an accident, resulting in the bursting of a wheel case and the flooding of the power house, very recently occurred in the Clinton dam power house of the Metropolitan waterworks in Massachusetts. The attendant lost control of the water-wheel gates in shifting from governor control to hand control. The wheel case was a perfectly good

one, and the ruptured iron was of ample thickness for normal conditions, and showed no flaw. If the wheel case had not let go, the penstock would have done so. It is always possible for the connections between the governor and the gate rigging to break, or for an attendant to lose control of the gates, resulting in a very rapid closure of the water-wheel gates. In the above plant the same operation of shifting from governor control to hand control had been performed safely for years, but at last the unexpected happened.

10. Where the penstock is long, is it not more conservative to provide means whereby the total pressure may be limited to a safe value rather than to rely upon predetermined arbitrary values of T and h which may not obtain under accidental conditions?

11. We should not forget that our penstock is full of water in motion. The water weighs 4,908,000 lb. When moving at a velocity of 10 ft. per second it contains 13,860 hp.-sec. of kinetic energy. This energy is a very real thing. You cannot destroy it. If you stop the water column you have got to expend this energy somewhere. There is only one place where it will be expended, and that is upon the water wheel. Even the small amount of this energy which will be expended in compressing the water and in stretching the penstock walls will very quickly reappear as power in the water wheel.

12. Our water column will develop, through a turbine of 80% efficiency, 3570 hp. If you throw off that amount of load from the turbine you have got to stop the water column as quickly as is feasible, otherwise the turbine will run away. But you are not only throwing off 3570 hp., of load, but at the same time you are supplying the turbine with 13,860 hp.-sec. of energy in addition to its rated capacity under normal head. How about the speed regulation under these conditions? It may be argued that the water column will not be completely arrested. Perhaps so; but that would only minimize the above troubles somewhat. To calculate it here would be beyond the scope of this letter, and would not modify the general argument.

13. Again, if you suddenly throw on a load of 3570 hp., with the water column at rest, the accelerating water has got to develop 13,860 hp.-sec. of energy upon itself before the water wheel can develop full power. If the turbine gates were opened wide instantly, the water column, starting from at rest, would acquire 10 ft. velocity in 6.2 sec., or, if starting from a velocity of 2 ft. per second (which might be velocity at friction load), in 5 sec. We cannot, of course, open the gates instantly. Here we are up against regulation and fly-wheel difficulties again, if the plant is to be subject to large and sudden load changes.

14. It begins to look like a surge-tank and fly-wheel proposition. The commercial load changes which will occur, the speed regulation which will be tolerated, and the permissible investment in surge-tank and fly-wheel effect, must all receive very careful consideration before the time of turbine-gate closure or opening (which may very well be different) can be established.

15. Possibly, therefore, we cannot establish the proper value of T from a simple formula based on V and h which may, perhaps, become of relatively small importance in comparison with more weighty matters.

16. But it must not be argued from the above facts that Mr. Reeves' formula is not valuable. It is valuable, very valuable, but chiefly to calculate quickly what not to do, rather than what to do. If engineers of design would make this formula, in the various forms in which it appears in this discussion, their familiar working tools, the engineers who provide turbines, generators and auxiliary apparatus would not so often be plunged in despair by "specified penstocks."

Ashland, Mass. **ALLAN V. GARRATT.**

Hard-Surface Road Specifications of the State of Illinois

Sir—In *Engineering News-Record* of May 8, 1919, p. 905, Clifford Older, chief highway engineer, Department of Public Works and Buildings, Illinois, outlines the adoption by the State of Illinois, as a basis for all its rigid surfacings, of a standard concrete slab 7 in. at the side and 8 in. at the center, for 16- to 18-ft. widths, and states that "the only other types considered suitable for the primary road system of Illinois are monolithic brick and bituminous concrete on a concrete base."

Is it possible that the great State of Illinois is retrograding so far from modern designs and constructions as to overlook the absolutely established supremacy of reinforced concrete over plain concrete?

The writer quotes from the article in question:

"It is fundamental that the load-supporting capacity of a rigid pavement is dependent upon its transverse strength, and its transverse strength is measured by its thickness and the modulus of rupture of the material of which the surface in tension is composed."

The modulus of rupture or the transverse fiber strength of *concrete*, which is the material in question, we know is of far less importance than the crushing strength. In fact, it is practically about one-eighth of the latter, and, for this reason, a reinforcement in the bottom of the slab has been introduced to make the modulus of rupture in tension at least equal to the crushing strength; by this means a far thinner and more elastic and resilient body is produced, with great economic results.

According to the conclusions of committee No. 9 of the National Conference on Concrete Roads, 1914, concrete highways are subject to the following six causes of failure or unnecessary deterioration: (1) Changes in temperature; (2) variations in the percentage of moisture in the concrete; (3) defective foundation; (4) improper drainage; (5) insufficient thickness of slab to carry the traffic; (6) faulty construction.

Then follows: "It is necessary, therefore, in a pavement properly designed and constructed, to minimize the cracks resulting from the above causes, by embedding a reinforcement in the concrete, which will so distribute the tensile stresses as to prevent formation of larger cracks."

The same committee further recommends, in general, that all reinforcement should be about 0.1%, which, in the 1916 conference, was further specified.

As an example of the efficiency of such construction, the writer will refer to H. B. Bushnell's article in *Engineering Record* of Mar. 24, 1917, p. 464, as follows: "Twelfth Street, Cook County, Illinois, east of Hillsdale, presents a striking example of the settlement of a rigid pavement laid on a yielding subgrade. At this point the road extends through a slough for 600 ft., and the maximum settlement at the time the last levels

were taken (after 16 months) was 1.74 in. It still is in a very good condition." This concrete was of course reinforced.

The experimental concrete roadways built at Riverbank, Calif., in 1912, have also amply proved the superiority of reinforced-concrete roads after seven years' service. The experience with the concrete roads in Wayne County, Michigan, Owosso, Mich., Iron River, Mich., Davenport, Iowa, Oakland, Calif., and scores of other locations, furthermore, is, as everybody knows, entirely in favor of reinforcement.

While the writer would use a reinforcement of 0.2% per foot width of a slab, we will compare the cost of adding 0.1% of reinforcing fabric to a 6-in. slab with the cost of an additional 2-in. thickness or an 8-in. slab, as follows: $0.1\% \times 6 \times 12 = 0.072$ sq. in. or, say, A. S. & W. Co. No. 068 weighing 35 lb. per 100 feet. At 5c. per pound, laid, this means $9 \times 0.35 \times 5 = 15\frac{3}{4}$c. per square yard of pavement or base laid in position. Two inches of concrete per square yard will cost not less than

$$\frac{2}{12} \times \frac{6.75}{27} \times 9 = 37\tfrac{1}{2}\text{c. per square yard.}$$

And as to the comparison of strength and resiliency between a 6-in. reinforced slab and an 8-in. plain concrete slab, there can be no doubt. Furthermore, the reinforced-concrete base or slab meets, to a large extent, *all* the six causes for failure laid down by the National Conference on Concrete Road Building, while the plain slab meets none.

H. W. Skidmore's article, "Defects in Surface of Bituminous Pavement Due to Concrete Base," in *Engineering News-Record* of May 1, 1919, p. 878, also criticizes the cement-concrete base and suggests "a bituminous-concrete base rather than a rigid one." Why not a thinner, richer, but reinforced-concrete base?

What can possibly induce engineers of the highest standing in highway engineering to ignore all precedents absolutely, as well as one of the most important improvements in building construction?

E. LEE HEIDENREICH,
Kansas City, Mo. Consulting Engineer.

Sir—I have read with much interest the article by Clifford Older, chief highway engineer of Illinois, on "Illinois Adopts a Uniform Basis of Design for All Types of Rigid Pavement," in your issue of May 8. The article is carefully written, and the position of the author gives his opinion great weight. If his premises are accepted as being the fundamental ones to be used in the design of a pavement, his logic cannot be disputed. It would seem, however, that he ignores some phases of the problem which, if fully taken into consideration, might modify the conclusions.

Mr. Older states first, "it is not the primary function of rigid pavements to span soft spots in the sub-grade." He also says, "it is fundamental that the load-supporting capacity of a rigid pavement is dependent upon its transverse strength." The first statement is not open to debate, but the second opens up a field of discussion. A logical formula based on the second assumption is developed, which is used to determine the thickness of the pavement. In other words, the pavement is designed not for its primary function, but for an incidental condition.

The soundness for this conclusion is the one questioned. A pavement is being designed, not a framed structure. Probably Mr. Older and the other able engineers who have concurred in his conclusions had other sound reasons for adopting as a standard the 8-in. ½-, 7-in. concrete slab, but these reasons are not set forth, and it would seem questionable whether the structural theory should be the sole basis for determining the thickness of foundations for all types of rigid pavements.

The thought which occurs after study of the article is that it attempts to cure a defect by covering it up rather than by eradicating the cause. Logically, if later experience shows that the 8-in. concrete is not enough, the thickness must be increased to 9, 10 or 11 in. Just as logically, the redesign of a bridge failure would only require that the members be made heavier. Such a course would excite only derision.

The items entering into the construction of a road are material and labor. The material in the case of a concrete roadway consists of sand, cement, stone and water. The labor consists of grading, ditching and mixing the concrete. The labor of transportation is really a material item, and may so be regarded. In an average job, labor consists of 50% and material of 50% of the cost of the completed work. In a mile of average 18-ft. pavement costing $27,000, the material and its manufacture into the road will represent two-thirds of the total. Each additional inch of concrete will amount to not less than $2500, or from 9 to 10% of the total.

This sum, or a part of it, spent on the labor of more completely preparing the road for its wearing surface, would work wonders. It would provide for 10,000 lin. ft. of drain tile in place, the deepening of the side ditches, the raising of shallow fills amounting to an average of 1 ft. for an eighth of a mile. In designing drainage for city pavements, the total cost rarely amounts to more than 15 or 20% of the cost of the improvement. This includes cement jointed pipe laid at considerable depths, of large size (in place of side ditches) many catchbasins and manholes and, frequently, rather lengthy outlets. It is certainly to be doubted that similarly adequate drainage for a country road would increase the total cost more than 5%, taking into consideration the amount of drainage which it is now customary to provide.

It seems to me that the money spent in this way will go farther toward making a first-class heavy-traffic highway than increasing the thickness of the concrete. Rarely in my experience have failures been caused by lack of depth of the foundation. Even when apparently so, investigation has shown some other primary reason, generally faults in the drainage, but often, also, because of careless mixing of concrete. Our materials are usually first-class, but labor items do not come up to the same standard. For this reason the adoption of the mechanical type of tamper is a long step in advance, and, of itself, reduces the necessity for increasing the thickness of the slab.

Mr. Older, it would appear, passes rather lightly over the necessity for wider roadway widths with the statement that, as a great number of heavy trucks will monopolize the roads, they must be thicker. If the traffic is so heavy, should not the question of greater widths receive more thought? True, a 4-ft. wider pavement would cost considerably more than a 1-in. increase in the thickness, but ordinary traffic is entitled to consideration. Because of heavy traffic and

inadequate revenue, the City of Chicago has for some years imposed a wheel tax, graduated on the size of the vehicle. Should not some such form of tax be equitably assessed on traffic of the kind he has in mind, thus creating a fund to be applied toward the correction of the evil? A highway on which the traffic is so heavy that the pavement requires 10 in. of foundation certainly needs a wide roadway, and would justify almost any expenditure for drainage. How many asphalt city pavements in our heaviest-traffic streets in our largest cities have such a foundation? States St. in Chicago has not, and it has teemed with heavy-truck traffic on an asphalt wearing surface for the past 15 years.

In this discussion much has necessarily been ignored, but the main thought has been to show that as far as the published reasons are concerned, sufficient data have not been submitted to justify the increase in the standard thickness of the concrete, in preference to other methods which may be suggested. A rather cursory study would also seem to indicate that other types of pavement suffer by the Illinois decision, which was not the intention of the department, I feel sure.

Chicago, Ill. PAUL E. GREEN.

[The foregoing letters were submitted to Mr. Older for comment, and his reply to the letters follows.—EDITOR.]

Sir—I have read carefully the accompanying letters commenting on my article on pavement design. E. L. Heidenreich criticizes the design because no reinforcing steel is used. For flexural effect it would be necessary to use such steel in both top and bottom of the slab, as both positive and negative moments occur in every road slab. The negative moment is particularly important adjacent to cracks or joints and the edges of the slab. Even in heavily reinforced pavements built by this department cracks were not avoided. The amount of steel recommended by Mr. Heidenreich would have but little effect so far as increasing the flexural strength is concerned.

The total maintenance cost of concrete and brick slabs from two to six years old in Illinois, including the maintenance of cracks, has not yet reached $40 per mile per year; nor is the maintenance cost of the oldest roads greater than those more recently constructed. Illinois has for years been a leader in the use of reinforced-concrete bridges, and the use of steel in roads has been carefully considered and experimental reinforced sections built, but the use of this material has not been deemed of sufficient benefit in reducing the first cost or maintenance cost, to justify the additional expense.

I am thoroughly in accord with Mr. Green's remarks concerning drainage. The importance of proper drainage cannot be overestimated. The design of the concrete slab adopted by the Mississippi Valley Association of State Highway Departments was, however, considered by the association as being that necessary to support the expected loads on a subgrade drained as thoroughly as a justifiable expenditure will permit. This matter, of course, represents the judgment of the engineers who adopted the design, based on their observation and study rather than upon any theoretical consideration.

In this connection, it should be held in mind that many states, Illinois, included, at the present writing, have absolutely no provisions restricting concentration of loads on their highways.

I also agree with Mr. Green that where the traffic is heavy, wide pavements would largely eliminate the necessity of traffic following distinct lines. The law providing for a bond-issue system of roads in Illinois, however, provides for a maximum width of 18 ft., and, having been approved by the people, is not only irrepealable but cannot be altered in any particular.

CLIFFORD OLDER.

Chief Highway Engineer, Department of Public Works and Buildings.

Springfield, Ill.

Concrete Coating for Steel Floor-Beams To Prevent Corrosion

Sir—In looking over your issue of May 29, I was very much interested in the article on "Scrapping Tons of Good Highway Bridge Metal Because of Local Corrosion." While, at first thought, it seems that the officials in charge of highway maintenance, who, as a rule are not trained engineers, are responsible for not keeping the steelwork properly protected with paint, yet we all know the unfortunate tendency in connection with public work to praise the official who spends whatever money his local board may allow him on the parts of the highway which show, rather than spend it on getting at and cleaning up inaccessible points. The neglect of these, after all is said and done, will not appear for five or ten years after the commissioner is out of office. Such being the case, would it not be wise, both from the engineer's standpoint and also from the standpoint of public economy, to coat the floor-beams thoroughly, and also all parts of highway bridges which are not easily accessible, with concrete? The first cost would be a trifle more, but the saving in expense of cleaning and painting would more than counterbalance this additional first cost, to say nothing of the greatly increased life of the bridge which it would give.

This matter, I understand, is receiving considerable thought from some of the railroad officials, and might, with considerable advantage, be adopted in connection with all road work. There are, of course, cases where this simple protection has been tried with unsatisfactory results, but in these cases the dropping of the concrete was undoubtedly due to faulty details of construction, rather than to any internal weakness in this system of bridge preservation.

I have not endeavored to go into the above in a technical way at all but simply wish to bring up the question, which is very important but of which one, nevertheless, hears very little. A. B. TAPPEN,

New York City. Mitchell-Tappen Company.

Why Not "The Profession of Engineering"?

Sir—In your issue of May 29, 1919, p. 1079, T. L. Condron, chairman of the license committee, Engineering Council, gives a definition of "professional engineering." While the definition in itself seems to meet the requirements of the case, the term "professional engineering" is decidedly objectionable. Why not substitute therefor "the profession of engineering," and begin the definition thus: "The profession of engineering embraces . . . ?" W. CHASE THOMSON,

Montreal, Can. Consulting Engineer.

HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Pipelaying Cost Is Influenced by Many Conditions on Each Job

CONSTRUCTION cost is influenced by so many local factors that each job must be considered in the light of its own conditions, according to a paper presented at the meeting of the Iowa Section of the American Water Works Association by W. A. Judd, superintendent of water-works at Mason City, Iowa.

For instance, in the laying of a one-half mile stretch of 10-in. pipe in good clay in 1915, the cost of pipelaying was only 5c. per foot, due partly to the fact that the ditch stood up well, and 500 to 600 ft. per day could be laid. Another job in the same year was scattered in short pieces, laying 6-in. pipe at intersections preparatory to paving. Here the cost was 7c. per foot, but excavation prices were lower on account of cooler weather and consequent higher labor efficiency.

On two jobs of laying 8-in. pipe in sandy clay, with an experienced gang in the first case and an inexperienced gang in the second, the costs were 32 and 40c. per yard for excavation, 13 and 16c. per yard for backfilling, and 3.7 and 7.7c. per foot for pipelaying. Weather and soil conditions influence such work, as is shown by records of 6-in. pipe laid behind a trenching machine. One job in wet, sticky clay cost 8.9c. per foot, bracing being needed close behind the machine, while with more favorable weather conditions on a similar job the cost was 6.4c. In good clay and with favorable weather the cost was 4c., but with the best weather of all the jobs, in a sandy trench, the cost was reduced to 3.2c. per foot.

For laying 6-in. pipe on all jobs during 1918 the average cost was 8½c. per foot, this reasonable rate, Mr. Judd explained, being due to the old and dependable emergency gang. On the other hand, earth excavation ranged from 42 to 66c. per yard, as compared with 32 to 40c. in previous years. In 1915 and 1916 labor was plentiful at 22½c. per hour. In 1914 and 1918 it was scarce at any price, and part of the time there was only the emergency crew of five men.

Methods of Shifting Pontoons for Walking Dragline Excavators

By Albert S. Fry

Morgan Engineering Company, Memphis, Tenn.

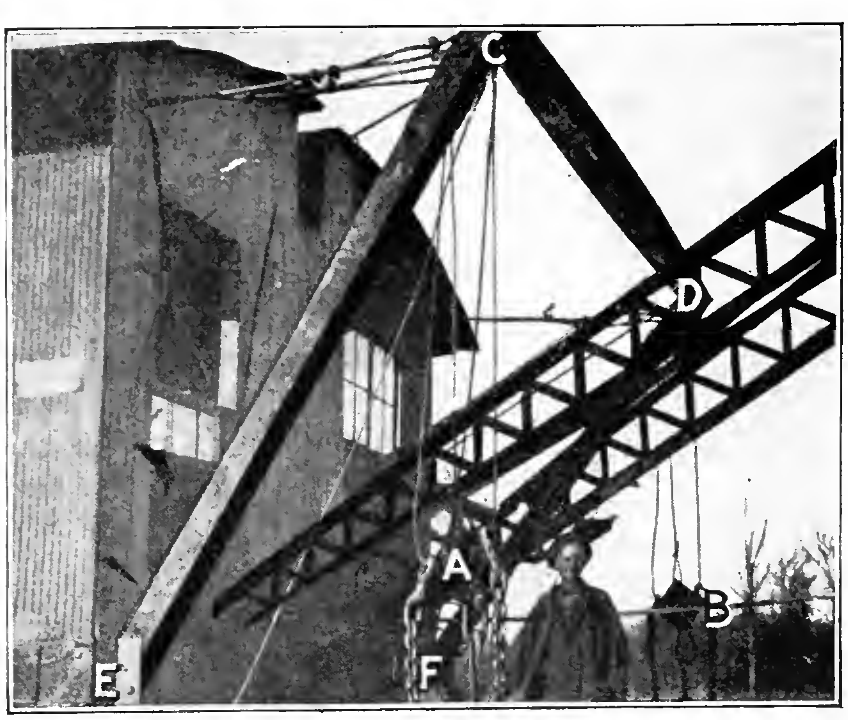
TWO successful methods of handling pontoons for walking dragline excavators were developed in the levee work for the Inter-River Drainage District in Missouri. Four excavators are being operated by the Callahan Construction Co., with J. W. Radford as foreman. The pontoons are 6 x 30 ft., and are built of 3 x 14-in. timbers.

The simpler method of shifting is to hook one end of the pontoon directly onto the bucket bridle. In this case, near one end of the pontoon there is a chain with a hook to be hooked to the bucket bridle. By the hoisting of the bucket the pontoon is raised from the ground, the machine is revolved, the drag cable tightened and the hoist line slacked until the pontoon is maneuvered into position on the opposite side of the machine. In shoving the pontoon up against the last one placed, the edge of the bucket is sometimes brought against the pontoon after it is unhooked and is resting on the ground.

The bucket is hauled in to the machine which pushes the pontoon up tightly against the last one. This practice is looked on with disfavor, however, as the bucket edge tends to damage the pontoon. Although a bit hard on the hoist cable, this method of handling pontoons is rapid and efficient.

An inclined gallows frame on the dragline is an essential feature of the second method. When this method is employed each pontoon is fitted with a U-bolt at each of its four corners.

Two blocks, which are shown herewith at A and B in the illustration, are triple-hitched to hoist cables which pass through sheaves at C and D, thence down to blocks at E and F and thence to a junction with each other in a common hook about midway between E and F. To lift a pontoon, bridle chains from A and B are hooked into the U-bolts. Then the common hook of the two hoist cables is connected to the bucket bridle. Tightening the bucket hoist line raises the pontoon, and the revo-



AUXILIARY FRAME ON DRAGLINE SHIFTS PONTOONS FOR WALKING DRAGLINE EXCAVATORS

lution of the excavator body carries the pontoon to the front of the machine. This method is much more cumbersome than the first and takes more time. After trying out the two methods, Mr. Radford has adopted the first method for all four machines.

In connection with the pontoons, it may be noted that one man is kept busy cleaning mud off the tops; if this is not done the tub of the machine will slip on the mud when the machine moves.

Concrete Used to Line Temporary Diversion Channel

By Glenn D. Holmes
Chief Engineer, Intercepting Sewer Board, Syracuse, N. Y.

Temporary diversion channels, for the unwatering of Onondaga Creek in the City of Syracuse, N. Y., in connection with the extensive improvements of the waterway being made by the Intercepting Sewer Board, are being constructed of concrete by John Young, the contractor. It was intended at first to construct these diversion channels of timber, but when excavation for them was opened up, well graded sand and gravel suitable for concrete was encountered, which led to the change in plan. The adoption of concrete resulted in a saving in width of excavation, and ordinary rather than skilled labor could be employed for the construction.

CONCRETE-LINED DIVERSION CHANNEL AT SYRACUSE

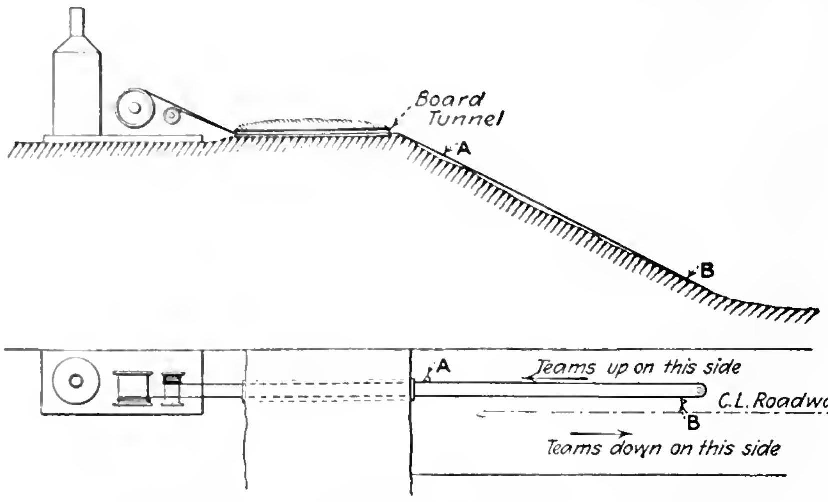
There are two of these channels, each about 1200 ft. in length. They will divert the water to the large storm sewer and around the work of construction. The larger of these channels is rectangular in section, 6 ft. wide and 3 ft. high, and has a capacity of about 250 sec.-ft. The smaller channel is U-shaped in section, 45 in. in height and top width, and has a capacity of about 50 second-feet.

Onondaga Creek has a drainage area of about 100 square miles. Its dry-weather flow reaches a minimum of about 50 sec.-ft. and its maximum dis charge has reached 5500 cu.ft. per second.

Snatch Cable Aids Teams on Steep Grade

Teams hauling earth from a portion of the river-channel widening work being done at Columbus, Ohio, are helped up a 15% grade by a snatch rope operated by a double drum hoist, as indicated by the accompanying diagrammatic sketch. From one drum the rope extends down the hill, and there makes a loop and returns to the other drum. By alternate forward and reverse operation of the drums the hitches at A and B see-saw up and down hill, one always being at the bottom when the other is at the top. From the drums the rope passes under the roadway through a small plank tunnel.

When a loaded team comes from the shovel to the bottom of the hill the driver makes a chain

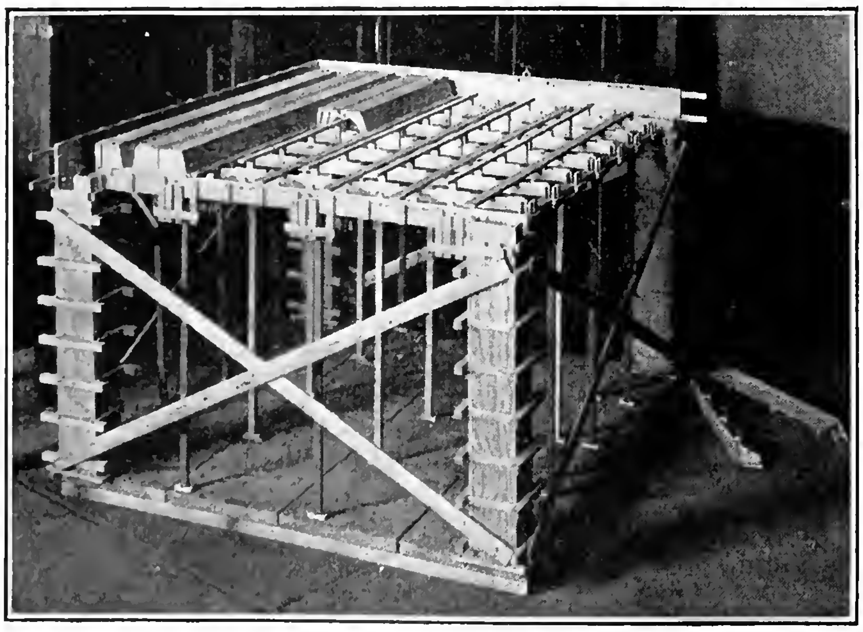


LOOPED CABLE HAULS WAGONS UP INCLINE

hitch from the cable to the rear axle and the load is snatched up the incline; the team is thus relieved of all work of pulling.

Model of Typical Concrete Form Section Helps Contractor

In building a new reinforced-concrete apartment house at Salt Lake City, Utah, Villadsen Brothers, Inc., the contractors, introduced a number of novelties in the design of the forms. Previous to the construction, the firm built the small-scale model of a typical form panel shown in the accompanying view. This was



MODEL ON SCALE OF 1½ INCHES PER FOOT

on a scale of 1½ in. to the foot and reproduced in precise detail the intended structure. The contractors state its cost was negligible compared with the total form cost, but that it has proved of great assistance to the form designers in studying the most economical connections and in forecasting the stripping of the forms.

It is also stated that the model has proved even more valuable, since the construction was completed, in the analysis of all suggestions and criticism following the actual work.

New York Wages Doubled in Four Years

A report issued by the New York State Industrial Commission states that during the four years since March, 1915, wages have increased on the average 107% and the number of employees 18%. In March, 1919, there were 9% fewer workers in the factories in the state than in the same month in 1917, but the payrolls were 27% larger.

Progress Report of Development Committee of American Society of Civil Engineers

Statement of Fundamentals on Which Views of Members Are Desired Includes Relations with Other Societies, Internal Relations and Local Associations, Technical Activities and Public Service

(By Wire from Minneapolis)

UNDER date of June 16, the development committee of the American Society of Civil Engineers, after a four-day session at Minneapolis, presented to the board of direction a report expressing certain fundamentals which the committee anticipates will form the basis of its ultimate report. The committee, desiring to learn the views of the membership on these fundamentals, suggested to the board that it take steps to secure these views. Accordingly, the board ordered the report printed for distribution at the business meeting of the society in Minneapolis the following day.

The report also carried the information that a committee of three, consisting of Gardner S. Williams, George G. Anderson, and Richard L. Humphrey, had been appointed to serve on a conference committee, with representatives of the development or aims committees of the national societies of mechanical, electrical and mining engineers.

The report in full follows:

The basis of the report herewith is the work of the four subcommittees which were appointed at the November meeting, and the main subdivisions represent approximately the scope of the subcommittee work.

A. Relations with Other National Societies and Related Organizations

It is the opinion of your committee that the identity of the four existing national societies should be preserved. The committee believes that the American Society of Civil Engineers should continue to pursue the objects for which it was formed as expressed in the constitution, namely, "the advancement of engineering knowledge and practice and the maintenance of a high professional standard among its members," and that it should devote its chief endeavors to the performance of these objects.

We feel, however, that the time has now come when this society should adopt the principle of becoming an active national force in economic, industrial and civic affairs.

This can only be done effectively, however, by active coöperation with other engineering organizations of the country. To this end the committee recommends that a comprehensive organization be formed embracing:

The local affiliation of the branches of the national technical societies and the local technical societies;

A state council composed of representatives from the local affiliations;

A national council consisting of representatives of the national technical societies and from the state council or state group organizations, in lieu thereof.

The object of the council shall be to increase the usefulness of the engineering profession, to bring about greater coöperation and to advance the welfare of engineers.

The council shall have an executive committee, shall maintain a central office and shall hold at least one meeting each year. It would be desirable that a bulletin of general engineering interest be published by the council. The council shall be supported by a per capita contribution or in such other manner as may be determined.

B. Internal Relations and Local Associations

Your committee makes the following recommendations:

Local Associations—That every member of the society be a member of a local association.

That there be created in each geographical district of the society an organization consisting of representatives of the local associations in that district.

That local associations and district organizations shall operate under uniform constitutional provisions to the extent only that the same are necessary or desirable to insure uniform relations with the society.

That the representatives of each district on the board of direction and the nominating committee of the society be elected by ballot by the corporate members resident in such district.

That it be the duty of each director to visit each local association in his district at least once during each calendar year.

That the nominating committee select candidates for the offices of president, vice-president, and treasurer, the election of which officers shall be by the ballots of the corporate members.

That there be an annual conference of representatives from the local associations for the purpose of discussing the welfare of the society and its members.

That there be allotted a percentage of the dues of the society to each district organization and each local association for the payment of their expenses.

That the board of direction refer for recommendation each application for membership to the local association in whose jurisdiction the applicant resides.

That the present provisions of the constitution relating to the discipline and expulsion of members be so revised as to make them more effective.

That it be the obligation of each local association to bring about within its territory a close affiliation of all branches of the national and of the local technical organizations for the purpose of advancing the status of the engineer.

That in communities where members are too few to form a local association, it be their obligation, in addition to that of their district local association, to affiliate with the resident members of other technical societies, and other engineers, where such affiliations will promote the organization of a local affiliate body.

That the local affiliations be the basis for comprehensive state and national organizations.

Rearrangement of Grades—That the grades of membership be more clearly defined and that changes be made in the grades of associate and fellow.

Student Societies—That it be the duty of the local associations to organize and assist student engineering societies in neighboring engineering schools, to provide carefully selected speakers, and to maintain personal contact with such societies.

(Note: The above is recommended in lieu of establishing the grade of student member and of establishing student branches.)

Young Men of the Profession—That it be the duty of the local associations to provide for the welfare of the younger members of the profession by:

1. Reasonable representation on the active committees.
2. Encouraging their discussion of the general problems of the society.
3. Arranging excursions to works of engineering interest.
4. Promoting social intercourse between them and the older members.

Personal Service—That a personal-service bureau be maintained by each local affiliation, so organized as to operate in connection with a central service bureau to be maintained by the national council.

American Engineers in Foreign Service—That it be the duty of members resident in foreign countries outside of North America to form associations and to promote an

affiliation with the resident members of other American technical societies.

That the board of direction consider the feasibility of keeping on record, and providing to American consuls abroad, the names, addresses and brief professional qualifications of members of the society resident abroad.

C. Technical Activities

Meetings—That local associations should hold not less than four stated meetings per year and encourage joint meetings with kindred societies.

That the fortnightly meetings of the parent society should be discontinued.

That the semi-annual meetings of the parent society should be supplemented by the addition of a spring and fall meeting held successively in different sections of the country under the auspices of a local association.

Papers—That the present system of securing papers depends wholly upon voluntary offers and results in a limited variety of subjects. Committees of the parent society and local associations should be formed and charged with the responsibility for promoting greater activity and discussions. Simultaneous discussions of important papers by local associations is desirable.

That the use of the monthly *Proceedings* should be extended to include editorial work, abstracting and reviewing important engineering articles and subjects of popular interest to the great majority of engineers.

Committees—That there be created advisory standing committees of the board to promote the study of important engineering subjects and charged with outlining and coördinating the work of like committees of the local associations. Three members of the board should constitute a standing advisory committee on each subject. Local associations should urge the younger members to identify themselves with local committee work.

That local associations should suggest names of volunteers possessing necessary qualifications for special committee service, and that tenure of committee membership shall terminate automatically on account of absence or inactivity.

That the society support an active program of research work, coöperating, if practicable, with existing research agencies.

That the chairmen of the standing advisory committees of the board should constitute the publication committee.

That to effectively carry out the intent of these recommendations a technical editorial staff under the direction of the publication committee should be established.

Sections or Divisions of the Society for Specialized Lines of Work—It is not recommended that the work either of the parent society or the local association be divided in this way. The object apparently sought by such divisions will be better met by the work of strong committees.

Coöperation With Specialized Engineering Societies and Other Organizations—Much of value has been accomplished in the past in this way and it is recommended that such work be continued and extended.

Standards in Engineering Practice—There exists at the present a committee known as the American Engineering Standards Committee, composed of representatives of the national engineering societies. This line of coöperation and advice is approved, and it is recommended that it be continued and extended, but the idea of developing this committee into another association is deprecated.

It is recommended that a book of recommended practice and standards be compiled which shall be revised periodically to follow the development of engineering.

D. Relation to Public Affairs

Definition of Engineering—That the three main ideas in a complete definition of engineering should be as follows:

1. A general and descriptive statement.
2. The content of the profession—the things that engineering does.
3. The aims and motives the profession should have.

Ethics—That a short code of ethics of broad scope, general character, and positive rather than negative injunction, be prepared.

Engineering Education—That a standing committee of seven be created to consider questions of educational policy, and offer advice and guidance in carrying out such policy. The aims of engineering education, fundamental requirements, changes in curricula indicated by changing social and industrial conditions, the qualifications of teachers, and the standardization of degrees, are a few of the topics which such a committee should rightly consider. Further, that local associations appoint similar committees of three or five to coöperate with educational institutions in their respective territories.

Licensing—That the society, in coöperation with the other founder societies, prepare a standard form of bill for the licensing or registration of engineers, to be used in the framing of legislation.

Arbitration and Expert Testimony—It is the belief of the committee that the present practice with regard to expert estimony and arbitration is not satisfactory, and it is recommended that a committee of the American Bar Association be asked to coöperate with the joint committee from the four founder societies, in order to develop better practice along these lines.

Publicity—It is recommended that the preparation of general articles on engineering subjects be encouraged and assisted by the profession, especially with a view toward having such articles published in the standard magazines.

Washington Agency Recommended

Legislation and Development of Natural Resources—It is recommended that the national council maintain an agency in Washington, D. C., or elsewhere, for the purpose of keeping advised of all proposed Federal legislation and departmental rulings and regulations involving, directly or indirectly, questions of engineering; and that such agency keep the society or its locals advised from time to time of such matters. It shall also be the duty of the various locals to keep advised on all proposed state legislation affecting engineering matters, and the said locals shall actively interest themselves to the end that proper legislation may be enacted. It is also recommended that such agency, and the state and national councils, shall keep advised as to the proposed creation of Federal and state commissions, whose activities may affect engineering enterprise; and that the influence of the locals and the society at large shall be directed toward securing the appointment of engineers upon such commissions.

The Service of the Engineer to the Community, State and Nation—The engineering profession owes a duty to the public which it is believed can best be discharged by the active participation of every engineer in the civic work of his locality. To this end it is urged that the engineer join the civic body of his community, and, if there be no such organization, that he should then endeavor to organize the community for civic work, in sympathetic coöperation with the governing body. The engineer's duty to the public also requires that he give his best efforts to matters of state, interstate and national character, calling upon the various engineering bodies for assistance and coöperation when necessary.

Patent Law—Inasmuch as a nation-wide society of inventors has been formed, composed largely of engineers, one of whose objects is to handle the subject of patent law, it is recommended that no action be taken on this subject at the present time.

Coördination of Government Activities—It is recommended that the influence of the entire membership of the society be directed toward the creation of a Federal Department of Public Works, the secretary of which shall be technically qualified and a member of the President's cabinet, and that the law creating such department shall provide for the coördination of all Government engineering activities.

Industrial Affairs—That fundamentals of industry and their inter-relations are based on engineering principles which form a part of the education of the engineer.

NEWS OF THE WEEK

New York, June 19, 1919

$200,000,000 French Contract to American Firm

Vulcan Steel Products Company Engaged to Rebuild Nancy District—Large Organization Required

That the Vulcan Steel Products Co., 136 Liberty St., New York City, has just received a cost-plus contract, valued at $200,000,000, for rebuilding the Nancy district of France, was made known to a representative of *Engineering News-Record* yesterday morning in an interview with the officer of the Vulcan Co. who arrived here this week, after closing the contract in France. Plans for a part of the project are on the way to the United States. The preliminary work of accumulating an organization and obtaining bids on machinery and equipment of all kinds will be started at once, so that the actual construction work may go forward the moment the peace treaty has been signed. Another retarding factor is the present high rate of exchange.

Associated with the Vulcan Steel Products Co. are MacArthur Brothers and the McClintic-Marshall Co., which will handle the construction work. French labor will be used, and it is understood that preference will be given to French manufacturers of machinery. However, a vast amount of American machinery will be bought.

Industrial Needs Paramount

Although the contract covers all classes of construction, particular attention will be devoted to industrial works, because of the revenue they will produce. For example, it is estimated that 5000 breweries have been destroyed. If only 20% are rebuilt, it will mean a thousand such plants. In that event it is quite likely that some American manufacturer of brewing machinery will become associated with the Vulcan Co. The same may happen in connection with the cement, textile and other industries. It is possible that a French company will be formed to handle the work over there for the Vulcan company.

Some time ago newspaper despatches stated that Europe intended to do its own rebuilding, without foreign assistance. It is now recognized that the task is far beyond the capabilities of post-war Europe. The plans for reconstruction are prepared by local committees. The French Government recognizes these committees as being responsible bodies. The Nancy contract was let by the committee in that district.

Report of Development Committee Discussed at Civil Engineers' Convention

Committee To Draft Another Report Before November 1, Based on Views of Members—Lively Two-Hour Discussion

(By Wire from Minneapolis)

Delayed two years by the war, the forty-ninth annual convention of the American Society of Civil Engineers convened in Minneapolis June 17. The main topic of the business session was the development committee's report.

At the opening session the visitors were welcomed by Governor Burnquist, and the president delivered the annual address (given in full on page 1208 of this issue). He was followed by Francis C. Shenehon, who in an address of singular charm spoke of the engineering features of the Twin Cities and their tributary territory.

Prompt Action on Report

The afternoon session, except for some routine announcements, was given over to a discussion of the development committee's report, which, though presented only the day before to the board of direction, had been put into type and distributed to the members. In presenting the report the secretary announced that the board desired that it be given careful study by the members and that they communicate their views to the chairman or the secretary of the development committee as early as possible. It is the hope of the board that the response will be such that the committee will be able to draft a subsequent report, final or progress, and submit it to the board by Nov. 1. That will allow of its distribution in ample time to have full discussion thereon at the annual meeting in January. (The report in full will be found elsewhere in this issue.)

Despite the fact that the weather was sweltering, and that the members one by one discarded their coats until all were coatless, including the president, discussion of the report continued for full two hours. In general, there was indorsement of the fundamentals laid down by the committee, and in every case full appreciation of the great amount of work done by the committee in drafting the document. The members of the development committee, on request of the chair and voluntarily, gave emphasis to certain sections of the report and enlarged on the committee's reasons for the recommendations.

Gardner S. Williams, of Detroit, expressed the view that two chief features of the report were the recommendations: First, that of election of directors by districts and the district organization scheme, and, second, that the society retain technical matters as its chief function, leaving to a separate system of organization the civic and welfare activities.

Robert A. Cummings, of Pittsburgh, pointed out the very distinct departure in the philosophy of the organization involved in the building from the bottom up in the plan for civic activities. The organization for technical work, on the other hand, he felt, is properly built from the top down, since technical work necessarily involves standards which are set at the top. Prof. George F. Swain, of Boston, felt that the section on licensing gave implied approval of the licensing idea with which, he said, he was not in agreement. He thought that a code of ethics should be negative in statement, and brief.

Lewis D. Rights, of New York, raised the question of the method of obtaining funds for the proposed enlarged activities. He asked whether an increase in dues to $25 for all members should be considered, and stated that the publication committee had thought of proposing to raise revenue by inserting advertising in the *Proceedings*. To this question of raising funds George G. Andrews, of Los Angeles, made answer that he felt certain the needed funds would be forthcoming when the members received the large measure of service provided for in the recommendations.

Needs of Young Men Discussed

William Anderson, as did other members, stressed the need for making adequate provision for the young men—in fact, no section of the report received such repeated emphasis. On the question of licensing, Mr. Anderson believed the society must meet it eventually and should address itself immediately to the problem in order to meet it with the greatest intelligence.

Charles Hansel, of New York, speaking of the section on the civic duties of the engineer, urged that, however it might be rewarded, it should carry the thought that each engineer had a duty as a citizen to become a member of the civic association of his community.

Following the program of the meeting, as outlined, the president's reception was held Tuesday evening. The other events of the meeting promised to be well attended, a large number having signified their intention of making the trip to Duluth and the iron range at the week end. E. J. M.

Southwestern Water Works Annual Meeting in Kansas City

The eighth annual convention of the Southwestern Water Works Association, to be held in Kansas City, Mo., June 23-26, as previously announced in these columns, will be devoted largely to round-table talks bearing on various current water-works problems. They will include practical five-minute talks by superintendents and members of the association on difficulties that have arisen in their experience, and methods for overcoming them.

Among the formal papers that will be presented at the meeting are: "Some Economies That May Be Effected in the Operation and Maintenance of the Water-Works System," by Homer V. Knouse, of Omaha; "Water Purification and Treatment," by D. H. Hunter, of St. Louis; "Sterilization of Water and Sewage," by Dave Morey, Jr., of Dallas, Texas; "Municipal and Private Utilities Versus the Consuming Public," by Charles Ade, of San Antonio, Texas; "What Constitutes a Water-Works System," by Clarence E. Ridley, of Port Arthur, Texas; "Waste Control by House Inspection with District Metering," by E. W. Case, of New York.

The round-table talks will include discussion of such subjects as benefits to be derived from monthly and quarterly reports by superintendents to their boards, monthly meetings of all employees to further coöperation, and cost of meter upkeep.

The Railroad Administration has granted a special round-trip rate, for delegates, amounting to 1⅓ one-way fare.

Changes in Texas Health Board Recommended

Recommendations for a department of sanitary engineering in the Texas State Board of Health, appointment of an experienced sanitary engineer as one member of the board, and a six-year term for board members, are included in the report of the Texas Public Health Commission appointed by Governor Hobby in November, 1918.

More Aqueduct Power Bonds

Aqueduct power development will proceed at Los Angeles, following a vote on June 3 of some 16,500 to 21,200 in favor of the issue of \$11,000,000 bonds for municipal purchase of the distributing system of the Southern California Edison Co. and \$2,500,000 for power-plant extensions along the aqueduct. The voters also authorized the sale of surplus power by the city to outside communities.

Contributions by Engineers, Architects and Constructors' Conference on National Public Works

M. O. Leighton, Chairman.

PUBLISHER'S NOTE: The space occupied under this caption is donated to serve as a means of frequent and intimate communication between the Engineers, Architects and Constructors' Conference on National Public Works, and the members of the profession. The contributor takes full authority for the statements made.

The Reply of the Corps of Engineers, United States Army:

The long-expected response of the Corps of Engineers, United States Army, to the activities of the engineers, architects and constructors of the country looking toward the establishment of a National Department of Public Works, has been made. It is in the form of a bill designated S. 1376, 66th Congress, First Session, introduced into the Senate June 5, 1919, by Senator Ransdell of Louisiana. It may be inferred that this senator is not prepared to father the measure, for the customary legend at the head of the bill contains the additional words "by request," after Senator Ransdell's name.

The bill is 35 pages long and contains 29 sections. It proposes to create an "Auxiliary Engineer Corps" in the United States Army for duty on works of public improvement—a noncombative corps of engineers which shall be "under the command and direction of the Chief of Engineers, U. S. A. . . . Its personnel shall be assigned by the Chief of Engineers to duties under his charge; specifically, on river and harbor improvements, inland waterways, locks and canals, fortifications, embankments, levees, dikes, breakwaters, piers and in the supervision and *in the construction of* national highways and bridges, and to any other public work that shall be now or hereafter assigned to the Chief of Engineers under the War Department. This organization shall also perform the duty of guarding and protecting all national public works."

Whether or not the foregoing language places the construction of national highways and bridges under the Chief of Engineers and thereby increases the authority of the Engineer Corps beyond that now conferred upon it is a question for the lawyers to determine. It may be observed, however, that, even if such authority is not specifically conferred, the language creates an "open sesame" and one is reminded of the ancient legend concerning the camel who received permission to place his nose in the tent. The bill is too long and comprehensive to be reviewed adequately here, but those who read it will have no question that it is the first step in the attempt, of which many of us have been aware, to militarize the public-works functions of the Federal Government.

The Engineers, Architects and Constructors' Conference on National Public Works took action at the recent Chicago meeting directly opposite in spirit and purport to that proposed under S. 1376. Therefore, the officers of this federation are in duty bound to oppose this bill. In order that the engineers, architects and constructors of the country may be informed concerning the first steps taken in opposition, the letter from the chairman of the conference to the chairman of the Senate Committee on Commerce (the Hon. Wesley L. Jones is chairman of the committee), to which the bill has been referred, is reproduced below:

MY DEAR SENATOR JONES:

On June 5 Senator Ransdell introduced into the Senate, "by request," a bill to create an Auxiliary Engineer Corps in the United States Army for duty on works of public improvement. It is numbered S. 1376 and has been referred to the Committee on Commerce.

I have the honor to be chairman of a federation of societies with an aggregate membership of 105,000 engineers, architects and constructors. This federation, which is known as the "Engineers, Architects and Constructors' Conference on National Public Works," is opposed to the provisions of the bill above-named, and at its convention in Chicago, Apr. 23-25, adopted a program contrary thereto in all respects.

On behalf of the federation aforesaid, I respectfully request that when the Committee on Commerce designates S. 1376 for hearing, said federation be given an opportunity to prepare and present its views.

For more than forty years the engineers, architects and constructors of the United States have almost unanimously been advocating the consolidation of the engineering and construction work of the Government into a Department of Public Works. The United States stands practically alone among the great and small nations of the world in that it has no such department. The matter has been considered and acted upon from time to time by various engineering societies throughout the country, but all efforts have heretofore been futile, for two reason: (a) The engineers, architects and constructors of the country have given local and sporadic rather than united and continuous support; (b) the Corps of Engineers of the United States Army has always been able to defeat any proposal that has thus far been advanced to Congress. The engineers, architects and constructors of the country are now united, and they propose to present to Congress in the near future a well considered plan for a Department of Public Works that will correct the present chaos in our national construction matters and achieve economy and efficiency.

I will not burden you now with a detailed statement of the reasons which, after more than forty years of mature consideration by well balanced men, prompt the forthcoming recommendations. With respect to S. 1376, we shall in due time endeavor to substantiate our belief that there is no more sure, certain and insidious way of accomplishing militarism in the United States than through the militarization of our public works. Heretofore, this militarization has extended principally to the rivers and harbors operations, with results that have repeatedly been characterized in a way not at all favorable to the Corps of Engineers. The bill S. 1376 extends Army control to public roads, bridges "and any other public work that shall be now or hereafter assigned." This bill is merely a part of a very ambitious plan to place the Army in the saddle over all engineering operations of the Government.

The genesis of S. 1376 is well known. You will find attached hereto a sample of propaganda circulated among the civilian force of the Corps of Engineers through the district office in New Orleans. It is hardly necessary to remind one as familiar with official Army procedure as yourself that no civilian attached to the Corps of Engineers would be so venturesome as to distribute this amazing circular without "knowledge and consent" of headquarters at Washington.

It is a very long way from the War Department to the capitol if one goes via

(*Continued on page* 1234)

To Arbitrate Jurisdictional Building Strikes

Engineers, Architects, Contractors and Labor Unions in an Agreement to Prevent Source of Trouble

Organized labor, through the American Federation of Labor, has joined with the large building employers' association, the American Institute of Architects, and Engineering Council, to form a board to arbitrate the so-called jurisdictional strikes which make up so large a part of the labor trouble in building operations. This board is to be known as the National Board for Jurisdictional Awards in the Building Industries, and consists of eight members, three to be selected by the building-trades department of the American Federation of Labor, and one each by the American Institute of Architects, Engineering Council, the Associated General Contractors of America, the National Association of Builders' Exchanges, and the National Building Trade Employers' Association.

Against Sympathetic Strikes

According to the constitution which was drawn up and adopted at the recent meeting of the American Federation of Labor, the duties of the board shall be to hear claims for jurisdiction over work performed by building trades and to determine by which trade the work in contention shall be performed, and to make an award in conformity with the facts submitted by the contender. At least a two-thirds majority of the voting members of the full board shall be required to render an award, in all cases.

The constitution as adopted further provides that when a dispute arises, the employer to whom the work has been given shall proceed with such workmen as in his judgment he may see fit to employ, pending a decision of the board, but the right of any contestant to the dispute shall not be prejudiced in its claim for a final award. Each signatory to the agreement agrees that the membership of its organization shall not take part in sympathetic strikes in any case of jurisdictional dispute. The constitution further provides that local organizations signatory to the agreement shall secure the enforcement and compliance of their organizations with the provisions of the agreement and the awards of the board. Local organizations refusing compliance with the provisions of the agreement and the awards of the board are to be suspended from their international organization, and the international organization shall proceed at once to man the job and the employer shall coöperate with the international organization in so doing. Any architect, engineer or employer represented on the board through an organization signatory to the agreement shall be suspended from his organization upon failure to comply with the provisions of the agreement and the awards of the board.

Water Purveyors Hold Thirty-Ninth Convention

American Water Works Association Reviews War Conditions and Looks Into Future—Rates, Prices, Hydrant Damages

Goodly numbers in attendance, a wieldy program well handled, an unusually large and varied exhibit of water-works appliances, a notable committee report on private fire protection services, much attention to war and after-war phases of water-supply, and a paper giving promise of a new and unique reciprocating pumping engine, were features of the convention of the American Water Works Association held in Buffalo last week. A number of the papers read are abstracted on pp. 1193-1198.

Effects of the War

Impressions left by a review of some five hundred court and commission decisions affecting water-works were presented by Leonard Metcalf, consulting engineer, Boston, Mass. Summarized, these impressions were:

"Public ownership is less attractive to the people in light of recent experiences." Commission jurisdiction is becoming more complete. The tendency is for the commissions to consider original cost "the fairest measure of value," but "many competent observers believe that past valuations or rating bases have frequently been too low." The older commissions generally recognize going value. Franchise values have shrunk materially in this as compared with the previous decade. The treatment of depreciation "has improved immensely." There is a marked improvement in the distribution of the water-works burdens between private consumers of water and the general public.

A review of water-rate decisions given in "Public Utility Reports Annotated," for 1915 to 1918, shows increases granted to four plants in 1915, 12 in 1916, 15 in 1917 and 67 in 1918. The lag between mounting expenses and grants of rate increase was 12 to 18 months. Although there were many substantial increases, commissions did not grant relief from increased war burdens to utilities generally.

The larger part of Mr. Metcalf's paper was devoted to a somewhat detailed study of the effect of the war upon water-works revenues and expenses. That portion of the paper appears in abstract on p. 1193.

In the course of the discussions on Mr. Metcalf's paper, R. B. Howell, of the Omaha Water District, said that 1917 was a very prosperous year for his works. Although rates were again reduced, a profit was shown. After questions by various members had been answered by Mr. Howell, it was remarked by J. N. Chester, of Pittsburgh, that the secret of Omaha's success is that it has municipal ownership under the sort of management more common to private ownership. Mr. Chester also stated that rate increases depend more upon political conditions than upon the necessities of the case. J. W. Ledoux, of Philadelphia, and others, complained of the slowness of the utility commissions in rate cases.

Besides the data and opinions given in Mr. Metcalf's paper, Charles Wood, of Philadelphia, submitted a number of opinions gathered by him: A representative of the manufacturers of cast-iron pipe reported that there had never been a time when the stock of water and gas pipe was so low as now. The president of one of the largest cement companies said cement has fallen at some points and there may be a further decline, but it is safe to say that the price of cement will never go down to its old level.

High prices, he added, are world-wide and apply to all commodities. The editor of *Iron Age* called attention to the large percentage of labor entering into the cost of pig iron, which makes against the lowering of the prices of this commodity.

New Price Level Now

Still another summary was presented by Edgar A. Buttenheim, editor of the *American City*, who said that the gist of the results of his investigations is that although there are all kinds of water-works construction in sight, there is too much disposition to wait a little longer in hopes of lower prices. It must be realized that we are on a new and higher scale of price levels. Dennis O'Brien, of the A. P. Smith Manufacturing Co., said that a questionnaire sent to members of the Water-Works Manufacturers' Association disclosed much independence of thought on prices. There is an undoubted feeling abroad that if one waits long enough a considerable reduction in prices will be seen. In opposition to this the economists, reasoning from the volume and movement of the circulating medium, predict continued high prices. The plain business man sees loss of laborers through war and immigration, high cost of transportation, and a demand for goods to make up for slackened production and normal increase. The shelves of the country are bare. Labor prices will go up rather than down. So, finally, the business man reaches the same conclusion as the economist.

Maj. E. C. Church, U. S. A., of New York City, urged that attention be given to deferred maintenance, which should now be taken up even if prices are high.

Instead of the association having a "Superintendents' Day," parts of several sessions were set aside for the discussion of subjects of appeal to the superintendents, and ample opportunity was afforded for question-box discussions.

The net result was small except under the set topic, that of damages to fire hydrants by motor vehicles. This was

opened by W. W. Brush, of New York City, who said that nearly 400 hydrants out of a total of 40,000 are damaged yearly by motor vehicles in his city. Repairs are generally made by removing and welding the standpipe. Welding alone costs $6 when done by the city and $8 or more when done in a private shop; digging up and resetting the hydrant, yard assemblage and cartage bring the total cost of repairs up to $25 to $30. There have been breaks where the hydrants were provided with fenders. In fact, protection against the heavy motor trucks now in use seems impossible. F. W. Cappelen, of Minneapolis, said fenders had not been successful there. His hydrant breaks due to motor vehicles had been 1 to 150 hydrants. Most of the breaks had been at street intersections. No one present seemed to favor the use of either flush hydrants or hydrants at the building line.

Brief Mention of Papers

Filtration of the Buffalo water-supply, said Henry F. Wagner, must wait for a reduction of the present excessive consumption, after which mechanical filters may be built on land near the pumping station, now partly under water. Some air-lift pump installations and the use of the air lift in connection with water treatment, where aëration is needed, were described by John Oliphant, of the Sullivan Machinery Co., Chicago.

Army and related water-supplies received an entire session. W. H. C. Ramsey, designing engineer, outlined the principles used in design, and described in detail the water-supplies of the many housing projects of the United States Shipping Board. Lieut. Col. Dabney H. Maury stated that the water-supplies of our cantonments and other camps served 4,000,000 troops and 2,000,000 civilians, without a single known case of water-borne typhoid, and with a very low fire loss. Lieut. Col. F. W. Scheidenhelm told how water was provided for the First Army while at the front in France. These three lantern-slide talks having held the attention of the convention through a whole session, the fourth paper scheduled for that sitting was thrown back to the next day, when William J. Orchard, manager Wallace & Tiernan Co., Inc., New York City, described the motor-mounted water-purification plants and laboratories used at the front—to which, it may be noted, Colonel Scheidenhelm gave praise.

Although the aim was to provide only 2 gal. of water to each man at the front, and sometimes only a fourth of that could be delivered, the task was not a small one, according to Colonel Scheidenhelm.

In the St. Mihiel drive the number of men supplied with water was 30 times as large as the civilian population of the district. The general plan followed was to have reconnoissance parties locate and test available supplies in advance of the occupation of a district. Collecting and distributing centers were called "water points." Here water, provided by gravity or pumping, and treated as might be necessary, was delivered to water tanks or cans on motor trucks, or other vehicles, or in some cases to tank cars running on light railways. The water so hauled was delivered directly to the soldiers or else to improvised storage, sometimes holes in the ground lined with tarpaulin; or canteens might be filled from storage tanks supplied by gravity or pumping. Under still other conditions, Lister bags, mounted on tripods, were used for the disinfection of water and its delivery to canteens. Soldiers in trenches were supplied from large water bags which were carried on the backs of men.

Reports of Special Committees

Had it not been for the valuable monograph designed to be the final report of the committee on private fire protection service, submitted for the committee by Nicholas S. Hill, Jr., chairman, the past year would have been almost barren of results so far as the technical committees of the association are concerned. This report makes an illustrated pamphlet of 58 pages. The various physical and financial questions involved are reviewed, and specific recommendations as to each are made. Much hearty commendation of the report in general followed its reading. Objections were made to some of the conclusions. In order that these objections, as well as written discussions yet to be received, might receive full consideration, and the whole be crystallized and the association take a final and positive stand on this vexed subject, which for years has occupied much of the time of conventions, it was voted to continue the committee, instead of adopting the report and discharging the committee, as the latter had proposed.

In behalf of the American Committee on Electrolysis, Alfred D. Flinn and Edward E. Minor submitted a progress report. The joint committee representing various utilities has conferred with the Bureau of Standards. A technical subcommittee has been created, and a plan has been formulated under which experts would be engaged to study electrolysis. The committee proposed that the American Water Works Association authorize the employment of an expert, but the matter was referred to the executive committee for consideration, in view of possible risks of commitments that might affect litigation.

The committee on revision of standard specifications for cast-iron pipe reported that no meeting has been held during the year but that it hoped to submit something for consideration next year.

The committee was continued, as was also the committee on form of contract and bond.

A canvass of ballots showed that a total of 382 votes had been cast for new officers, with almost unanimous choices, as follows: President, Carlton E. Davis, chief of the Bureau of Water, Philadelphia; vice president, Capt. M. E. Worrell, Q. M. C., formerly of the Meridian, Miss., water-works; treasurer (reëlected), J. M. Caird, chemist and bacteriologist, Troy, N. Y.; trustees, W. H. Randall, superintendent of water-works maintenance, Toronto, Ont., and F. C. Jordon, secretary of the Indianapolis Water Company.

Montreal was selected as the next meeting place, its chief rival being Detroit.

The financial condition of the association was reported as being favorable. The investment fund has reached $13,000. During the year which ended Mar. 31, 1919, there was a net loss of 39 in membership, attributable to the war. The membership on that date totaled 1241, of whom 1024 were active, 91 corporate, 121 associate and five honorary. Taking figures compiled as of September, the membership for the past five years has been 1136, 1229, 1361, 1360, 1308. Geographical sections on Apr. 1, 1919, were: Canada (not officially organized), California, Central States, Four-State (parts of New Jersey, Pennsylvania, and all of Maryland, Delaware and the District of Columbia), Illinois, Iowa, Minnesota, New York State (with part of New Jersey). The committee recommended that state sections be organized whereever the state membership was as many as twenty.

Report on the "Journal"

The publication committee reported that after several months' effort it succeeded in getting original contributions for the *Journal*. The social value of association membership is not sufficient to hold members. It was recommended that a larger amount of original matter be secured for the *Journal* and that it be published six instead of four times a year, at an estimated cost of $7500 a year. This was approved.

A ride on the lake with a visit to one of the Buffalo pumping stations was provided by the City of Buffalo. At the station a 3,000,000-gal "Unaflow" pumping engine (see p. 1193) was seen in operation. A trip to Niagara Falls, a smoker, and special entertainment for the ladies were provided by the Water-Works Manufacturers' Association, Charles R. Wood being chairman of the entertainment committee. Another committee of the same association, with Burt B. Hodgman as chairman, deserves special mention for the unusually large and varied exhibit of water-works appliances.

Conference on Public Works

(*Continued from page* 1232)

New Orleans. The engineers, architects, and constructors of the country are coming to the doors of Congress very soon, with a respectful petition which will be the result of forty years of the best engineering thought. But, in so doing, we shall remember the fundamental engineering axiom that a straight line is the shortest distance between two points.

Reference in the foregoing letter to organized propaganda will be made

clear by the following reproduction of the circular sent out from the district office of the Engineer Corps at New Orleans:

Strictly Personal

1. The purpose of this letter is to enlist all chief clerks in the United States Engineer Service in a "push" to shove a bill through Congress for mobilizing an Auxiliary Engineer Corps. A bill for this purpose was recently placed in the hands of Senator Joseph E. Ransdell, with a view to having it introduced by request at the coming session of Congress. This bill provides for a complete organization from top to bottom—non-combative with a military status and under the direction of the Chief of Engineers, U. S. A., with the rank he now has, major general, and the division engineers with the rank of brigadier general, and the district engineers with rank of colonel; with provision for ranks for assistants below the district engineer. The corps is to be mobilized from the *experienced* men of *all* classes in the office and field now in the service. Its duties are as now—construction, care of maintenance of public works; and national highways and bridges to be added. Let us talk about national good roads; absolutely necessary for the welfare and prosperity of the nation.

2. The foundation of this organization rests solely upon merit, in which the lowest paid man, if he is made of the right stuff, has a chance to make something of himself. It is not a salary grab, nor does it provide any fat jobs.

3. It provides for a three-year practical training period for all who enter the service and who have had no previous engineer experience, before a man can get into the permanent corps, unless he qualifies for a commission before that time.

4. It provides graded pay in the various classes of the personnel, and also longevity pay of 5% increase for every three years' service, for eight 3-year periods; besides the opportunity, if qualifications justify it, for promotion from class to class with higher pay in such class. It provides also for an efficiency board that shall pass upon the qualifications of the personnel, so that justice is done to all men; with reference to duties performed and rank and compensation, which any member of the corps is justly entitled to. I may perform the same duties as junior engineer which you perform as inspector. The inequality of grade and pay is apparent.

5. As the honor men of West Point furnish the personnel for the Army engineers, so shall the honor men of our schools and colleges furnish the personnel of all departments of office and field service, for the Auxiliary Engineer Corps, through the three-year training period.

6. The district engineer is the commanding officer of the district, and the contracting officer, with division of duties under several departments each in charge of experienced assistants under him.

7. The duties of custodian of property and disbursing officer will be divorced from the duties of district engineer, leaving the hands of the latter untied for strictly engineering duties. No corporation would think of merging the duties of chief engineer with that of treasurer or paymaster.

8. Now then—it is essential to watch progress at Washington. Essential to have the bill introduced in the coming session, and essential to keep it going till passed.

9. *When you hear* that the bill is introduced, call on your Congressman or Senator for printed copy.

10. Talk for such legislation—be enthusiastic over it—get your business friends to write letters requesting the passage of the bill. Keep at it and don't let it rest. It will take time to get the bill through.

11. It may be necessary to keep a man in Washington under pay to "*mark time*" and keep a sharp lookout. All the engineering district, I feel sure, will rally to the necessary financial assistance.

12. If you are really interested, send a self-addressed envelope, $3\frac{1}{2}$ in. x 9 in. with 3c. postage stamp affixed, for copy of "Reasons Why an Auxiliary Engineer Corps Should be Mobilized at This Time." Any further "dope" desired will be furnished, but always send self-addressed stamped envelope.

13. Later on, if you desire it, we will have the bill cyclostyled. This work, with a copy of the brief mailed flat, will cost about 15c. for postage and paper.

14. It is desired to work and talk quietly among the employees and our friends in each district—though the New Orleans *Times-Picayune* recently published something about the proposed legislation. I feel sure the district engineers do not care to have anything to do with this legislation one way or another. They are trained to do their duty and not be relieved from it. If things have gotten into a deep rut, any relief needed must come through the people and Congress; so it is up to us to take the initiative. Strong influence is working to turn public works over to the Quartermaster Corps because they have already so many of our men in the service, and there is talk of a waterways commission and a construction engineer branch in the Quartermaster's service; but it is not believed that either the people or Congress are ready for a change of engineers. The Auxiliary Engineer Corps will meet any public necessity if there is one, for a waterways commission. There is a chance for any engineer that knows anything about river and harbor work to get in, as it calls for men having this special qualification, and where he will have every opportunity to make use of it. Let us work for it. Personal work among ourselves and friends, and before Congress, will be of much value.

Address, John D. Schmidt, 519 Canal St., New Orleans, La.

National Service Committee Makes Report of Activities

At the recent regular meeting of Engineering Council, the National Service Committee reported that since the Chicago conference on a national Department of Public Works held last April (see *Engineering News-Record* of May 1, 1919, p. 857) the work has been divided into four parts: (1) Organization of executive and finance committees; (2) drafting of a bill; (3) organization of a campaign committee, and (4) a review of public-works laws of other countries.

The Chicago conference appointed an executive committee, including Cass Gilbert, Morton C. Tuttle and W. O. Winston, who declined appointment; their places were filled by J. Parke Channing and W. H. Hoyt, of Duluth, and the National Lumber Manufacturers' Association is to name a member. The committee on text of bill has completed its labors, and it is the intention to consult leaders in Congress and obtain advice as to its introduction.

The campaign committee is still in process of organization, the desire being to obtain one or more members from each state in the Union. It was determined to create separate state committees, all synchronizing with the Washington office.

The review and compilation of the public-works laws of other countries are practically completed.

To coöperate with the state campaign committees and supply them with information and talking points, it is proposed to obtain a man with expert knowledge of Government procedure. The engagement of a publicity man is also proposed. The committee desires to conduct the campaign by avoiding objectionable methods of the past, and substitute therefor a campaign, conducted on a high and dignified plane, consisting largely of counsel given to members of Congress by their constituents—thoughtful, serious advice given in an individual capacity in much the same way in which an engineer or architect would advise a client.

In order to introduce Engineering Council to members of Congress and make known its purposes, a letter was addressed to the chairmen of various committees of the House and Senate. Appreciative acknowledgments have been received from a large number.

A regular monthly bulletin is now issued. It aims to cover the most important Governmental engineering work, the last one being a list of all engineering legislation which has been introduced into the 66th Congress and a brief discussion of the most important measures included therein.

Civil Service Examinations

United States

For United States civil service examinations, listed below, apply to the United States Civil Service Commission, Washington, D. C., or to any local office of the commission, for form 1312.

Assistant designing engineer, Naval Ordnance Plant, South Charleston, W. Va., \$9.20 per diem. July 8. File applications before July 8.

Valuation engineer, \$3600-\$4800 per year, and assistant valuation engineer, \$2500-\$3600 per year; technical staff, income-tax unit, Bureau of Internal Revenue, Treasury Department. No date specified.

Master computer, \$2400 to \$1800 per year, computer (Grade I) \$1800 to \$1400 and computer (Grade II) \$1400 to \$900, Ordnance Department. Applications will be received until further notice.

Assistant inspector of engineering material (aircraft), \$5.92 per diem, July 15. File applications before July 15.

Engineering Societies

Calendar

Annual Meetings

AMERICAN SOCIETY FOR TESTING MATERIALS; University of Pennsylvania, Philadelphia; June 24-27, Atlantic City, N. J.

AMERICAN CONCRETE INSTITUTE; 6 Beacon St., Boston; June 27-28, Atlantic City, N. J.

NEW ENGLAND WATER WORKS ASSOCIATION; Tremont Temple, Boston; Sept. 30, Oct. 1-3, Albany, N. Y.

The Engineers' Society of Milwaukee held its regular monthly meeting, June 11. It was addressed by G. G. Curtis, of the Bray Studios, Inc., New York City, who showed and described the films, "The Motion Picture's Secret Part in Winning the War" and "The Motion Picture of the Invisible," illustrating gasoline vapor, sound waves, electric current and other unseen forces.

The Western Society of Engineers was addressed June 9 by J. H. Waterman, superintendent of timber preservation, Chicago, Burlington & Quincy R.R., who spoke on "Results Obtained from Treatment of Track, Ties and

Bridge Timbers." The celebration of the society's 50th anniversary has been postponed until June 27-28. The first day's program will include the topics, "Fifty Years of Engineering Progress" and "The Engineer in War." On the second day there will be a basket picnic at the sand dunes on the south shore of Lake Michigan.

The West Virginia Engineers' Association was tentatively formed at a meeting held in Charleston June 8, at which a constitution and by-laws were adopted. No officers were elected at the organizing meeting.

The New England Water Works Association and the **Boston Society of Civil Engineers** will hold a joint field day at Pemberton, Mass., June 25, with dinner at the Pemberton Inn. The boat will leave Rowe's Wharf, Boston, for Pemberton at 10:15 a. m.

The New York Chapter of the American Association of Engineers was addressed June 11 by Maj. David A. L'Esperance, who spoke on "The History of the 15th New York Regiment." the meeting was also addressed by A. H. Krom.

The Engineering Society of Akron, Ohio, held its first annual banquet June 10, at which E. E. Workman, president of the Akron Chamber of Commerce, spoke on the proposed city plan for Akron.

The Louisiana Engineering Society was addressed June 9 by Thomas L. Willis, city engineer of New Orleans, who spoke on garbage disposal, with particular reference to conditions in New Orleans.

The Montreal Branch of the Engineering Institute of Canada gave a dinner to Brig. Gen. Charles H. Mitchell, C.M.G., D.S.O., June 12, on the occasion of his return from overseas. General Mitchell gave an account of his experience and the part played by the engineering branch of the service on the other side of the ocean in winning the war.

Personal Notes

FRANCIS C. SHENEHON and ADOLPH F. MEYER have become associated under the firm name of SHENEHON & MEYER, consulting and designing engineers, with offices in the Metropolitan Bank Building, Minneapolis. Mr. Meyer enters the new firm from his work as special lecturer on hydraulic engineering at the University of Minnesota, having very recently served also as chief engineer and general superintendent of pulp and paper mills, Minnesota & Ontario Paper Co. He is a graduate in civil engineering, Wisconsin University, class of 1904, and has been engaged in engineering work, more particularly in the field of hydraulic engineering, since that date. From 1914 to 1917 he served as associate professor of hydraulic engineering, University of Minnesota, at the time when Mr. Shenehon was dean of the college. Since that time Mr. Shenehon has been engaged in a variety of work, in private practice, specializing largely in hydraulic engineering.

LIEUT. COL. DABNEY H. MAURY, Construction Division, U. S. A., who was advisory engineer for the original construction of water-supplies in the Army, and who recently received his discharge from the service, is in Chicago arranging for temporary consulting-office quarters. Several Eastern engagements prevent his resuming his former practice in Chicago for the time being, and he is at present making his headquarters at the University Club. Colonel Maury states that the advisory engineer's office handled 275 different projects, supplying 4,000,000 troops and 2,000,000 civilians. No typhoid fever has been attributed to the water furnished.

W. E. HART has been appointed district engineer in charge of the Minneapolis office of the Portland Cement Association, handling work in Minnesota and North and South Dakota. He has been connected with the association for the past two years, his work being principally in South Dakota. He was previously county engineer of Eddy County, North Dakota, and city engineer of New Rockford, North Dakota.

CAPT. LEVANT BROWN, Engineers, U. S. A., has received his discharge from the service and has become associated with the San Francisco office of the United States Bureau of Public Roads, as senior highway engineer. Captain Brown was with the Bureau of Public Works in the Philippines as a constructing engineer for ten years, before entering Army Service.

MAJ. SAMUEL W. FLEMING, JR., a member of the firm of GANNETT, SEELYE & FLEMING, of Harrisburg and Erie, Penn., who recently returned to this country from overseas, expects to receive his discharge at an early date. Major Fleming served with the 315th Infantry, and has been decorated with the Croix de Guerre and the Distinguished Service Cross.

PROF. CHARLES J. TILDEN, head of the department of civil engineering, Johns Hopkins University, has been called to the Sheffield Scientific School of Yale University as head of the department of engineering mechanics, and will begin his duties in that position next September. Professor Tilden has served for nearly six years as head of the department of civil engineering at Johns Hopkins. In February, 1917, he received his commission as a captain in the Engineer Officers' Reserve Corps and was ordered to active duty, but later returned to the inactive list to become secretary of the general engineering section, advisory committee, Council of National Defense. In May, 1918, he was appointed to the department of education and training, United States Shipping Board, Emergency Fleet Corporation, and was in charge of education and training work in Districts Nos. 8 and 11 on the Pacific coast. He returned to Johns Hopkins University in October last year.

LIEUT. COL. W. G. ARN, Engineers, U. S. A., recently received his discharge from the service, and has resumed his former work as assistant engineer, maintenance of way, Illinois Central-Yazoo and Mississippi Railroad System, with headquarters in Chicago. Colonel Arns entered the service on February, 1917, as captain in the Engineer Officers' Reserve Corps, and was called to active service in May and assigned to the 13th (Railway) Engineers. In March he was promoted to major, and in April, 1919, to lieutenant colonel of the same regiment. While in France he was located in the Verdun sector from September, 1917, to March, 1919, in charge of maintenance and construction work.

C. R. CUMMINS and N. F. BLAIR have become associated under the name of the CUMMINS-BLAIR CO., which will be affiliated with the present C. R. Cummins Co., with offices in the Leader-News Building, Cleveland. The new company will engage in reinforced-concrete and brick building construction.

LIEUT. COL. HAROLD TROTTER, D. S. O., has returned to Canada after several years' service at the front. Before the war he was a member of the firm of HENRY HOLGATE, consulting engineers, Montreal. He entered the war as a captain in the Canadian Engineers.

C. E. SHEARER, who for the past year has been engaged in bridge engineering for the Government of the Philippine Islands, has returned to his office in Memphis to resume private practice.

LIEUT. COL. GEORGE A. JOHNSON and MAJ. WEBSTER L. BENHAM, whose association in partnership under the firm name of JOHNSON & BENHAM was recently announced in these columns, have offices in the Firestone Building in Kansas City, Mo., and not in the Pathfinder Building, as previously stated. Colonel Johnson entered the service originally as officer in charge of the water and sewer section of the maintenance and repair branch of the Construction Division. Original construction of water supplies from the first was handled by LIEUT. COL. DABNEY H. MAURY, advisory engineer for water-supply of the Construction Division of the Army.

LIEUT. W. L. RHULE, Quartermaster Corps, U. S. A., who recently received his discharge from the service, has become associated with his father, George M. Rhule, in building construction, with headquarters in Altoona, Penn.

M. C. HUTCHINS, engineering department, Southern Railway, has been elected city engineer of Charlotte, N. C., succeeding J. C. CALDWELL, who has resigned to enter the contracting business of Caldwell, Thompson & Company.

JAMES A. SALTER has been appointed state architect of North Carolina, the appointment being authorized by the State Building Commission through act of the legislature creating the office.

L. J. DRIGGS, construction engineer, Pennsylvania Public Service Co., at Phillipsburg, has been appointed construction engineer, Citizens' Light, Heat & Power Co., of Johnstown.

FRANK T. SHEETS has been appointed designing engineer, Illinois Division of Highways, with complete charge of the design, preparation of plans and surveys of all roads and bridges constructed by the state.

CAPT. OMAR GASTON, Construction Division, U. S. A., who recently received his discharge from the service, has become general superintendent of building construction, Dahlman Construction Co., Milwaukee.

MANLEY OSGOOD, assistant plant engineer, Merchant Shipbuilding Corporation, Harriman, Penn., has been appointed chief engineer, Detroit Bureau of Governmental Research, with office at 100 Griswold Street.

MAJ. HERMAN F. DOELEMAN, Construction Division, U. S. A., has received his discharge from the service and has resumed his practice as a consulting engineer, with offices at 507 N. Charles St., Baltimore.

CAPT. JOHN K. WILLIAMS, Engineer Corps, American Expeditionary Forces, has received his discharge from the service and has accepted a position in the city engineer's department in San Diego, Calif.

J. H. BARNES and JOHN R. LESLIE have become associated under the firm name of the LESLIE-BARNES ENGINEERING Co., St. Joseph, Mo. Mr. Barnes has resigned as engineer of the city park board to devote his entire time to the new company.

LIEUT. JAMES FERGUSON has returned to Canada after four years' service overseas and has resumed his work in the engineering department of the Canadian National R.R., with headquarters in Montreal.

B. HAROLD WILLS has received his discharge from the Army and has returned to his former work in the engineer's office of Burlington County, at Mount Holly, N. J.

MAJ. D. D. GUILFOIL, 108th Engineers, U. S. A., who recently returned from France, has received his discharge from the service and has returned to his former work as sales engineer, SAUERMAN BROS., engineers and manufacturers, Monadnock Block, Chicago. The 108th Engineers, composed mainly of Chicago men, participated in the Somme and Meuse-Argonne offensives and, following the armistice, was a part of the army of occupation in Luxembourg.

L. R. WOODHULL has been appointed engineer, State Building Commission of North Carolina.

MAJ. E. J. COE has been appointed city engineer of Duluth, Minn., succeeding COL. LIONEL AYERS, resigned.

NILES C. SORENSEN, structural engineer and architect, has opened offices at 500 Congress Building, Detroit, for the practice of architecture and architectural engineering.

ARTHUR G. SKOUGLAND has been appointed engineer of the park board of St. Joseph, Mo., succeeding J. H. BARNES, resigned to enter private practice, as noted elsewhere.

G. W. COMSTOCK has been appointed county road engineer of Wetzel County, West Virginia, with headquarters at New Martinsville.

WILLIAM E. MITCHELL, 305th Engineers, has returned to Altoona, Penn., and will soon leave for Duluth to supervise construction work for R. C. Woods & Co., Camden, N. J.

T. H. JOY and H. E. GALLUP have announced the dissolution of the firm, the JOY-GALLUP Co., engineers and architects, Birmingham, Ala.

Asphalt Association Formed

Representatives of several asphalt-producing companies of the United States and Canada have completed the organization of an association, the title of which is to be "The Asphalt Association." Its purpose will be to disseminate information on the uses of asphalt, with particular reference to highway and street paving, coöperation with city, county and municipal officials and with scientific bodies and colleges seeking to bring about the most effective methods for the use of the material. The New York office will be located at 15 Maiden Lane. Other offices will be established soon in Chicago and Atlanta, and ultimately in other cities in the United States and Canada.

The following officers were elected for the ensuing year: President, J. R. Draney, general sales manager of the United States Asphalt Refining Co.; vice-president, W. W. MacFarland, assistant secretary of the Warner Quinlan Company; treasurer, N. G. Luykx, of the Freeport & Mexican Fuel Oil Corporation; secretary, J. E. Pennybacker, formerly chief of management of the United States Bureau of Public Roads, during the war period secretary of the United States Highways Council, and, more recently, director of roads of the American Automobile Association. Mr. Pennybacker will be the active officer in charge of the affairs of the association.

Exhibits Numerous and Varied at Water-Works Convention

Activity in the water-works field of engineering is indicated by the unusually large number of exhibits at the recent annual convention of the American Water Works Association in Buffalo, N. Y. The exhibits themselves were quite varied in character, covering practically every detail of apparatus, process and literature pertaining to the field. On account of the unexpected number of exhibitors, it was necessary to provide overflow exhibition rooms to accommodate them. The names of the companies which were represented are as follows:

National Water Main Cleaning Co.
Rensselaer Valve Co.
Pittsburgh Meter Co.
Engineering News-Record
The A. P. Smith Manufacturing Co.
Wallace & Tiernan Co., Inc.
The American City
Builders' Iron Foundry
Thomson Meter Co.
Gamon Meter Co.
Fire and Water Engineering
Lock Joint Pipe Co.
Municipal Journal and Public Works
Engineering and Contracting
Eddy Valve Co.
Buffalo Meter Co.
The Pitometer Co.
United Brass Manufacturing Co.
The Central Foundry Co.
Glauber Brass Manufacturing Co.
United Lead Co.
E. I. du Pont de Nemours & Co.
Union Water Meter Co.
Hays Manufacturing Co.
Pittsburgh-Des Moines Steel Co.
Birch-Hintz Manufacturing Co.
Lead Lined Iron Pipe Co.
Electro Bleaching Gas Co.
Modern Iron Works
Joseph Dixon Crucible Co.
W. & L. E. Gurley
Worthington Pump & Machinery Corporation
N. Mueller Manufacturing Co.
The Kennedy Valve Manufacturing Co.
Pittsburg Filter & Engineering Co.
Neptune Meter Co.
Water Works Equipment Co.
Ford Meter Box Co.
Multiplex Manufacturing Co.
Chicago Bridge & Iron Works
New York Continental Jewell Filtration Co.
Canadian Engineer
The Leadite Co.
H. W. Clark Co.
Hersey Manufacturing Co.
Sullivan Machinery Co.
Ross Valve Manufacturing Co.
Hauck Manufacturing Co.
The Garlock Packing Co.
McNutt Meter Box Co.
Bingham & Taylor
Simplex Valve & Meter Co.
Pennsylvania Salt Manufacturing Co.
National Meter Co.
Flower Valve Manufacturing Co.
Allis-Chalmers Manufacturing Co.
United States Cast Iron Pipe & Foundry Co.
Arnold-Hoffman Co., Inc.
El Ingeniero y Contratista
United States Rubber Co., Mechanical Goods Division
American Manganese Bronze Co.
Irving Iron Works Co.
Badger Meter Manufacturing Co.
Carbic Manufacturing Co.
Flexible Armored Hose Corporation
Darling Valve & Manufacturing Co.
Richardson Phoenix Co.
International Filter Co.
John Fox
Roberts Filter Manufacturing Co.
American Steel & Wire Co.
De Laval Steam Turbine Co.

Impostor Soliciting Loans

The Thomson Meter Co. issues a warning that an impostor is traveling through the New England States representing himself as a relative of a former officer of that company, and soliciting loans to pay hotel bills, railroad fare, etc. If he should call upon the reader, the company requests that

he be held on suspicion, wiring immediately to E. M. Shedd, 266 Brookline Ave., Boston, Mass., or the Thomson Meter Co., 100 Bridge St., Brooklyn, N. Y.

Government Surplus Materials To Be Sold in Seven Classes

Under arrangements made after the signing of the armistice to dispose of Government surplus materials with the least disturbance of normal business conditions, the director of sales, C. W. Hare, assisted by a score of assistants, has classified under seven sections the materials to be disposed of. Each section is supervised by assistants chosen because of their previous familiarity with the commodities over which they have charge. These materials include those which had been contracted for previous to the armistice and which the Government was forced to take over when the signing of the armistice practically suspended operations in over 500 manufacturing plants throughout the country. Practically all these plants were turning out, as component parts or finished products, materials foreign to their peace-time production.

The various sections which will handle the materials as classified are as follows: (1) Contractors' and railway equipment and building material; (2) plant facilities, including completed and uncompleted manufacturing plants, warehouses, etc.; (3) machine tools; (4) motor vehicles, vehicles, and aircraft; (5) quartermaster stores; (6) ordnance and ordnance stores; (7) raw materials and scrap.

The actual selling of the surplus materials is to be done by the several bureaus of the War Department which holds title to the property to be disposed of. Sales will be made under the following rules: (1) For cash at auction; (2) to the highest bidder on sealed proposals; (3) at the current market price if there is an established market for such property and current market quotations accompany the report of sales; (4) by negotiations under competitive conditions and provided the price obtained is not less than the price fixed by appraisal, or is the highest of not less than three independent competitive bids.

Material-Handling Machinery Manufacturers Meet

Four sessions of a semi-annual meeting of the Material-Handling Machinery Manufacturers' Association were held June 10-11 at the Hotel Astor in New York City, with a large membership in attendance. Most of the time was given over to discussions of proposed publicity methods by which the attention of engineers and manufacturers could be brought to the advantages and economies of machinery instead of hand labor for handling all kinds of material, but an evening session was devoted to more general subjects, with special attention to machinery used in ports and terminals.

BUSINESS NOTES

THE BARBER ASPHALT PAVING CO., of Philadelphia, announces that, following the promotion of Charles W. Bayliss from manager of the street and road department to vice-president in charge of sales, the following changes in organization have become effective: J. E. Morris is appointed manager of the street and road department, Philadelphia, Penn.; H. M. Stafford succeeds Mr. Morris as assistant manager in charge of the Eastern district, with headquarters in Philadelphia; F. F. Massey succeeds Mr. Stafford as assistant manager in charge of the Southwestern district, with headquarters in Memphis, Tenn., and G. R. March succeeds T. H. Morris as sales manager of the Iroquois department.

THE WILLIAM B. SCAIFE & SONS CO., of Pittsburgh, Penn., manufacturer of steel buildings and bridges, transmission towers, and storage tanks for oil and water, announces the opening, July 1, of a Chicago sales and engineering office at 38 S. Dearborn St. Charles F. O'Hagan, formerly chief engineer of the company at Pittsburgh, will be resident engineer and manager.

THE BAILEY METER CO., of Cleveland, Ohio, announces that E. A. Hitchcock has become associated with the company as vice-president. He will supervise the training of technical graduates for the company's service and sales department. For the past six years he has been connected with the E. W. Clark & Co. Management Corporation in an advisory capacity. Previous to that time he was professor of experimental engineering at the Ohio State University.

THE BORDEN CO., of Warren, Ohio, manufacturers of Beaver easy-working die-stocks and square-end pipe cutters, announces that C. A. Greene, its Chicago representative, has opened a downtown office at 549 W. Washington Boulevard.

THE CHICAGO PNEUMATIC TOOL CO, Fisher Building, Chicago, Ill., announces that J. W. McCabe, who was district sales manager of the company at Buffalo, N. Y., has been appointed special representative for the foreign-trade department. The company announces also that W. H. White has been appointed acting district manager of sales at Buffalo during Mr. McCabe's absence on a trip to the Orient.

THE CHALMERS PUMP MANUFACTURING CO., of Lima, Ohio, announces that it has purchased the entire pumping machinery business of the Canton-Hughes Pump Co., of Wooster, Ohio. Beside C. F. Brown, president, and Fred Biszantz, secretary and treasurer, of the old Chalmers Pump & Manufacturing Co., Frank D. Shumate, of Chicago, has become associated with the company as vice-president and sales manager. Mr. Shumate has been connected with the Worthington Pump & Machinery Corporation for the past 13 years.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO. announces the appointment of H. L. Garbutt, for the past six years manager of the line-material section of the company at East Pittsburgh, Penn., as manager of the supply division of the San Francisco office. Mr. Garbutt was formerly in the sales organization of the Drew Electric & Manufacturing Co., of Indianapolis.

THE MACOMBER & WHYTE ROPE CO., Kenosha, Wis., has opened a branch at 30 Church St., New York City, under the management of E. E. Robirds; also a branch at Birmingham, Ala., in charge of James A. Boope, 805 American Trust Bank Building.

TRADE PUBLICATIONS

The following companies have issued trade publications:

THE AMERICAN DISTRICT STEAM CO., of North Tonawanda, N. Y.; catalog, 80 pages, illustrated; descriptive of central-station and interior heating equipment. Also a folder entitled "The Radiator Has the Floor," describing the "Adsco" vapor heating system.

THE HODGES STUCCO MACHINE WORKS, of Union Central Tower, Cincinnati, Ohio; pamphlet, 9 x 12 in., eight pages, illustrated; describes the Hodges electric stucco machine for applying stucco by centrifugal action.

THE WALLACE & TIERNAN CO., INC., of 349 Broadway, New York City; folder, 8½ x 11 in., 4 pages; states the necessity for sterilization of water supplies affected by spring rains and floods and advocates the use of liquid chlorine as the agent.

THE M. & M. WIRE CLAMP CO., 2 Fifth St., S. E., Minneapolis, Minn.; pamphlet, 3½ x 6 in., 15 pages, illustrated; describes the use of adjustable concrete form clamps.

THE CENTRAL FOUNDRY CO., of 90 West St., New York City; leaflet, 8 x 6 in., one page, illustrated; describes the use of "Led-Lok" for the connection of cast-iron soil pipe, consisting of a lead joint which is locked into the pipe.

THE HOOD MANUFACTURING CO., of 3227 First Ave., South, Seattle, Wash.; catalog, 7 x 10 in., 16 pages, illustrated; gives specifications for and illustrates the use of Hood tractors.

THE MCMYLER INTERSTATE CO., of Cleveland, Ohio; bulletin No. 40, 8½ x 11 in., 49 pages, illustrated; describes and gives layouts for the use of shipbuilding cranes.

Volume 82 | NEW YORK, THURSDAY, JUNE 26, 1919 | Number 26

Philosophy and Romance

SELDOM does one hear an address of such singular charm as that of Francis C. Shenehon, delivered before the annual convention of the American Society of Civil Engineers. His subject, "The Engineering Activities of the Twin Cities," invited a dry-as-dust treatment —a stringing together of facts and figures that would swamp the visitor but leave him impressed with the idea, however vague it might be, that he had come to a country of engineering wonders. Instead, the address has an irresistible pull, is inviting, not repelling, gives the basic reasons, geologic and economic, for the location of St. Paul and Minneapolis, and then paints the picture not only of what is but what may be in the future. The philosophy illuminates the romance and justifies the vision. We urge every engineer, no matter what his specialty or place, to read with care, and then reread, the address of Mr. Shenehon. It is not merely interesting and informative, but is an unusual model of something we sadly lack in our engineering writing—a technical theme handled with grace and charm, losing nothing of its technical value, but rather being enhanced by the treatment.

Precautionary Maintenance of Motor Trucks

MAINTENANCE is as essential to a motor truck as to the road upon which it travels. While this statement seems obvious, there is an abundance of ocular evidence that many contractors and other truck owners disregard it—in its preventive aspects, at least. This tendency is seen in the condition of tires which have been practically ruined by overloading, skidding, overspeeding, and misalignment of wheels. The reasons for this neglect are no doubt lack of understanding on the part of the owner of the cost of tires relative to other truck maintenance and lack of knowledge as to the principal causes of excessive tire wear. What may be the result of such abuse is set forth in an article by A. F. Masury on p. 1262. The facts presented are well known to tire and truck manufacturers and dealers, but it is doubtful whether the majority of truck operators realize that, normally, gasoline and tire costs are equal. Failure to grasp this fact is probably due to the insidiousness of tire wear. Gasoline waste is immediately apparent both in bills and decreased truck efficiency, but in tire abuse the damage occurs in a manner which is not noticed until the tire goes to pieces. Neglect of precautions against abuse leads to a tire cost which often outweighs the utmost possible extravagance in gasoline waste, an excess which is not realized unless accurate itemized cost data have been kept. In the absence of such data, particular attention should be given to preventing those conditions of truck adjustment and operation which are known to be destructive.

Another Joint Concrete Committee

THREE years ago the Joint Committee on Concrete and Reinforced Concrete completed its third and "final" report, and shortly thereafter its constituent committees were discharged by their respective societies. Since then the world has been too full of other activities to bother much about standard specifications. The final report was an admirable document, which, in spite of the rigidity and conservatism peculiar to the efforts of joint action, is recognized as having the authority it deserves. Nevertheless, the subject of concrete, like all other technical subjects, is moving, and fresh consideration of concrete specifications is now necessary. It is, therefore, pleasing to note that the American Society for Testing Materials, through its executive committee, has initiated action toward the formation of a new joint committee to prepare standard specifications for reinforced concrete, with the same constituent societies as were brought together in the older joint committee. This committee should be formed at once and should proceed immediately to work, for some time must elapse before a report can be expected from it. As was pointed out in these columns three years ago, the opportunity for some authoritative utterance on the manufacture of concrete is more important than one on the design. Much remains to be crystallized regarding concrete as a material. To this, it is hoped, the new committee will devote most of its attention.

"Movies" in Science

MOTION-PICTURE houses for some time have been showing pictures of what they call the "analysis of motion," in which well known actions, such as figure skating, sprinting and baseball pitching, are reproduced on the screen at one-eighth the actual speed of the performer. Every element of motion in these pictures stands out with snapshot clearness. Grace hitherto unsuspected is revealed, and the methods by which results are achieved are understood as never before. This latter phase has decidedly an engineering application in the development of motion study and its consequent readjustment of production methods. No false or unnecessary movement can escape detection, but at the same time the sense of motion, lacking in a series of snapshots, is always present. An analogy may be found in the system used by Nathan C. Johnson in studying the setting of concrete, as referred to on another page. While the popular "movie" film slows down normally fast processes, Mr. Johnson's automatic camera speeds up the normally slow, so that one can, for instance, observe in a few minutes the physical and chemical phenomena of many days. Motion pictures have already had a marked influence on social conditions; may they not nave a bright future in science?

The Development Committee's Report

WITH the presentation to the board of direction of the progress report of the committee on development, there devolves on each member of the American Society of Civil Engineers a duty to study the report in detail and to communicate his views to the committee. Such is the wish and request of the board. The report has been prepared by a body representative of the society geographically and in varying points of view. It is a crystallization of ideas that have long been developing and that have assumed their present form after some months of study and four days of the hardest kind of work in Minneapolis.

Though the resolution accompanying the document states that the report contains "certain fundamentals which it is anticipated will form the basis of its ultimate report," it is clear from the discussion in Minneapolis that the committee is open-minded. It is seeking the views of the members of the society. It wants to know what of the content of the report they consider good, what they wish modified or rejected.

Space does not permit either detailed analysis or discussion. In general, it will be conceded, we believe, that the report stands on solid ground. Such radical innovations as the proposal to consolidate the four leading societies into one or to make the welfare work supreme are rejected. On the other hand, there is recognition that all engineering societies need to be drawn closer together, and that present conditions require more attention to welfare work than was necessary in the past. The provision for these steps is made without interjecting elements that would lessen the society's prestige.

In the four major divisions of the report the controlling ideas are plainly evident. In the category of technical activities, the spirit is that of development of a fuller service to the membership, a service that shall include in well rounded fullness the wide scope of what is now termed civil engineering. Question must be raised as to the source of the funds for the proposed enlarged work, but that will necessarily have the detailed consideration of the committee if the plans outlined are approved.

As to internal affairs, the ruling idea is that of organization along the lines of our Governmental system, so that the members in each community and each district may come to know one another better and by better acquaintance work more effectively for the advancement of the engineering profession. An important feature in this section of the report is the emphasis on the need for taking care of the younger members—not merely of the society but of the whole profession.

As to external relationships, the recommendations look to a federation for civic work of all elements of the profession, the method of organization being from the bottom up—through the locals and the state organizations to a national council.

In regard to public relations there are three dominant points: Publicity, that the function of the engineer may become better known; vigilance and action in matters of legislation affecting engineers; and the duty of the engineer as a citizen. As to each of these major lines of activity much will, we hope, be said in the near future.

It is evident that the committee has pitched high its ideal for the society. Appreciating the quality and the size of the membership, it proposes a program that a weaker body could not or would not dare attempt. As to the vision, generally, there will probably be little disagreement. As to detail and method there will be differences of opinion, and on these differences the committee desires light from the members.

In considering the report, there are two important facts to be remembered: (1) Whatever plans are evolved from the work of the committee will have the backing of nine thousand engineers of a class whose individual achievements are a warrant of effective action once they place themselves back of a definite program; (2) the ultimate report, strong as it will be with the backing of nine thousand civil engineers, will not stand alone. The other three national societies have similar committees. The inevitable conference report which, obviously, will not touch the internal affairs of the individual societies, will have mobilized for it the strength of forty thousand leaders of the profession.

The report, then, is destined, when developed into its final form, to have tremendous influence. Progress in the Mechanical Engineers' committee has been sufficient to show that the thinking in that society on external and civic relations is along parallel lines. The same vision is controlling that has actuated the Civil Engineers' committee—a vision of enlarged service to the profession and to the community. The other societies, if their participation in Engineering Council is a criterion, will have similar views. Forty thousand engineers united in effective organization, with a vigorous program such as they have the ability and vision to draft, can do more for the members of the profession than any other agency. Therefore, it behooves the members of the American Society of Civil Engineers to express their matured views on the report. The committee on development has reached the point where it must have their help and counsel. After the members have responded, the program for action can be formulated.

Good Roads on Long-Term Bonds

NEW York State has recently had a change in its highway administration, and with it has come a change in highway policy. The former administration, against the advice of its engineers, leaned, latterly at least, to the construction of a large mileage of cheaper type of highway. The object, if one may put it so, was political rather than statesmanlike—the desire to satisfy the clamors of the populace rather than to give them that which the state's own experience had demonstrated to be the most economical in the long run.

Furthermore, under the New York law the state assumes responsibility for maintenance and rebuilding, once it has taken over a road. It is to the interest of the local community, therefore, to get as much mileage as possible. If that mileage be constructed with a surfacing that wears out in four or five years, or less, it is no concern of the local community, except in so far as it contributes to the general state tax levy. It is a bad business procedure for the state, however, not merely because the maintenance cost of heavily traveled roads is high, but because the state highways are financed by fifty-year bonds, and with a continuance of this procedure issue upon issue would be piled up to pay for surfacings that had disappeared.

The figures in the New York case are very convincing. In the period from January, 1915, to December,

1918, the maintenance on 284 miles of brick road cost $210 per mile per year; on 208 miles of concrete roads, $138; on 2793 miles of bituminous macadam, penetration method, $490; on 2451 miles of water-bound macadam, $911, and on 173 miles of gravel macadam, $843. All of these figures are for the maintenance of surfacing without the reconstruction of more permanent or expensive types.

With such experience data available, we are not surprised at the reversal of policy in the highway department. Henceforth, ultimate economy is to be looked to and the mileage that the local communities do get will, in wearing ability, bear some decent proportion to the life of the bonds under which they are financed.

No one in these days will defend fifty-year highway bonds, but, that being the law, it is plain that the highest type construction only should be allowed on the heavily traveled roads.

City Transit Concentration

CITY growth has changed the aspect of many transit problems since the inauguration of the earliest rapid-transit systems. Improved transit facilities, constructed because of growing congestion, have in turn attracted more business to their neighborhoods, and have further increased the crowding of business and of traffic. Today transportation is the throttling point of city activities; housing, heating and lighting, telephone and other services have possibilities which our present demands do not approach, while the transportation systems are seriously overburdened.

New problems have come into being with the change of conditions. On the one hand, the congestion of traffic that has been created must be dealt with; better means must be devised for handling the very dense traffic with which existing transit routes have burdened themselves. On the other hand, concentration of traffic by a few transit routes must be counteracted and distribution of business and of traffic brought about. In connection with both directions of development, the coordination between street and transit routes needs to be improved, and the condition of mob-like crowding which exists at the entrances to important rapid-transit stations must be relieved. Some, perhaps all, of the new problems of transit congestion are worth consideration in connection with the discussion of continuous-train service which appears on another page.

If the continuous-train system will solve a sore and extreme problem, like that of 42nd St., it has much larger possibilities. Its distinguishing characteristics are its great traffic capacity, and its distributed station service. When we are confronted by serious overloading both of rapid-transit lines and of their street approaches, these qualities give the "moving sidewalk" a commanding claim for attention in transit planning.

Relatively few engineers have concerned themselves broadly with transit problems in the past; in the future these problems will concern many. City passenger movement—both surface and rapid-transit—is in the field of the municipal engineer, for it deals with one of the most essential services in the city's existence. Hitherto not all municipal engineers have been sufficiently free of the pressure of the moment's duties to face resolutely the problems which the future will bring. Mr. Seaman's article may prove helpful, therefore, by picturing conditions of serious character which, though now restricted to only two or three cities, are likely to become much more general.

Of greatest value, perhaps, is the emphasis which consideration of continuous trains lays upon what may be called the crosstown traffic problem. Reference to the conditions existing in the southerly one-third of Manhattan Island will bring this problem most clearly before the mind, although it exists in every large city. It is the problem of delivering traffic to an area rather than to points along a line—in other words, of distributing from the trunk lines of transit; and in Manhattan this distribution is crosstown. The one- to two-mile width of the island is adapted for highest-grade business use over its entire width, yet in the past only the central axis has been so developed, while the outskirts, because distant from the central axis, were left to second- and third-class service. In earlier years, moreover, concentration of all major business along a single line was most in harmony with the needs of the business. But, many decades ago, the facilities of a single street were out-grown, and today the great need is for means of spreading the traffic from river to river.

Counteracting the natural tendency toward lateral spread, however, there has been in New York the obstacle of the growing difficulty of crosstown transit. In recent years this difficulty has become serious indeed. The problem has had some study by the rapid-transit construction authorities of the city, but action has ever been blocked by the greater pressure for improved longitudinal transit. It may be hoped that now, with the principal rapid-transit lines nearing completion, the formidable crosstown problem may be taken in hand again. And it may also be hoped that the lessons sure to flow from such study will be noted by the engineers of other communities with respect to their bearing upon local transit needs and plans.

In view of the large possibilities of the continuous-train system, it is remarkable that no trial installation has been made so far. Important objections to the system lie on the surface. There are undoubtedly great mechanical difficulties in the problem. Equally serious doubts may be entertained concerning the ability of a miscellaneous public to use a moving device. But both classes of doubt may be regarded optimistically. As concerns the adaptability of the public, the doubts indeed have largely been deprived of their force by the success attained with moving stairways; their heavy patronage, even in the stores where they are used by women and children almost exclusively, and are often without attendance, overthrows the fear that moving transit devices are dangerous. With respect to mechanical difficulties, the case may be considered in the light of other unpromising railway problems that have been worked out to complete, practical success. In short, the striking correlation between certain vital transit needs, on the one hand, and the improved facilities afforded by the continuous train, on the other, is bound to force the system into notice, and, while difficulties of serious character may be expected in applying it, they do not appear insuperable.

The 42nd St. problem is only one of a class of crosstown problems in New York. The city is a ribbon of parallel threads which lack the bonding strength of cross-connection. Complete control of the crosstown problem, if it can be attained, will create a new basis for the city's development.

Storing and Handling High Explosives During the War

Methods Developed by Ordnance Department in Taking Care of Vast Quantities of Ammunition Were Based on Safety Regulations and Modern Material-Handling Devices

By G. C. Munoz

Major, United States Army, Chief of Construction Section, Supply Division, Ordnance Department, Washington, D. C.

High explosives of the kind used in ammunition are rare commodities in peace times, but even their occasional use would seem to make it worth while to record for future reference the methods of handling and storage developed by the United States Army during the war. To assure the necessary steady flow of this ammunition to the American Expeditionary Forces, embarkation depots capable of handling a 30-day supply had to be built at seaboard points, remote from large communities and yet within the lighterage limits of the major ports from which the material was shipped. The principal problem to be solved in planning these depots was the adoption of standard types of magazines for the safe storage of ammunition, smokeless powder and explosives; the planning of terminal track and wharf facilities for the rapid handling of large amounts of ammunition; and the protection of the military stores from fires or from enemy attack.

Seven of these depots were established along the Atlantic seaboard; they were located as noted in the accompanying table. In addition, storage facilities were provided at the principal shell-loading and bag-loading plants, and since the signing of the armistice special depots for the storage of high explosives have been established in sparsely settled regions in the interior of the country. The tidewater depots were all designed in accordance with certain fixed standards which are given below, although, of course, in each case there were many variations in local conditions which required special detailing. The general layout of an ideal depot is shown in the accompanying drawing.

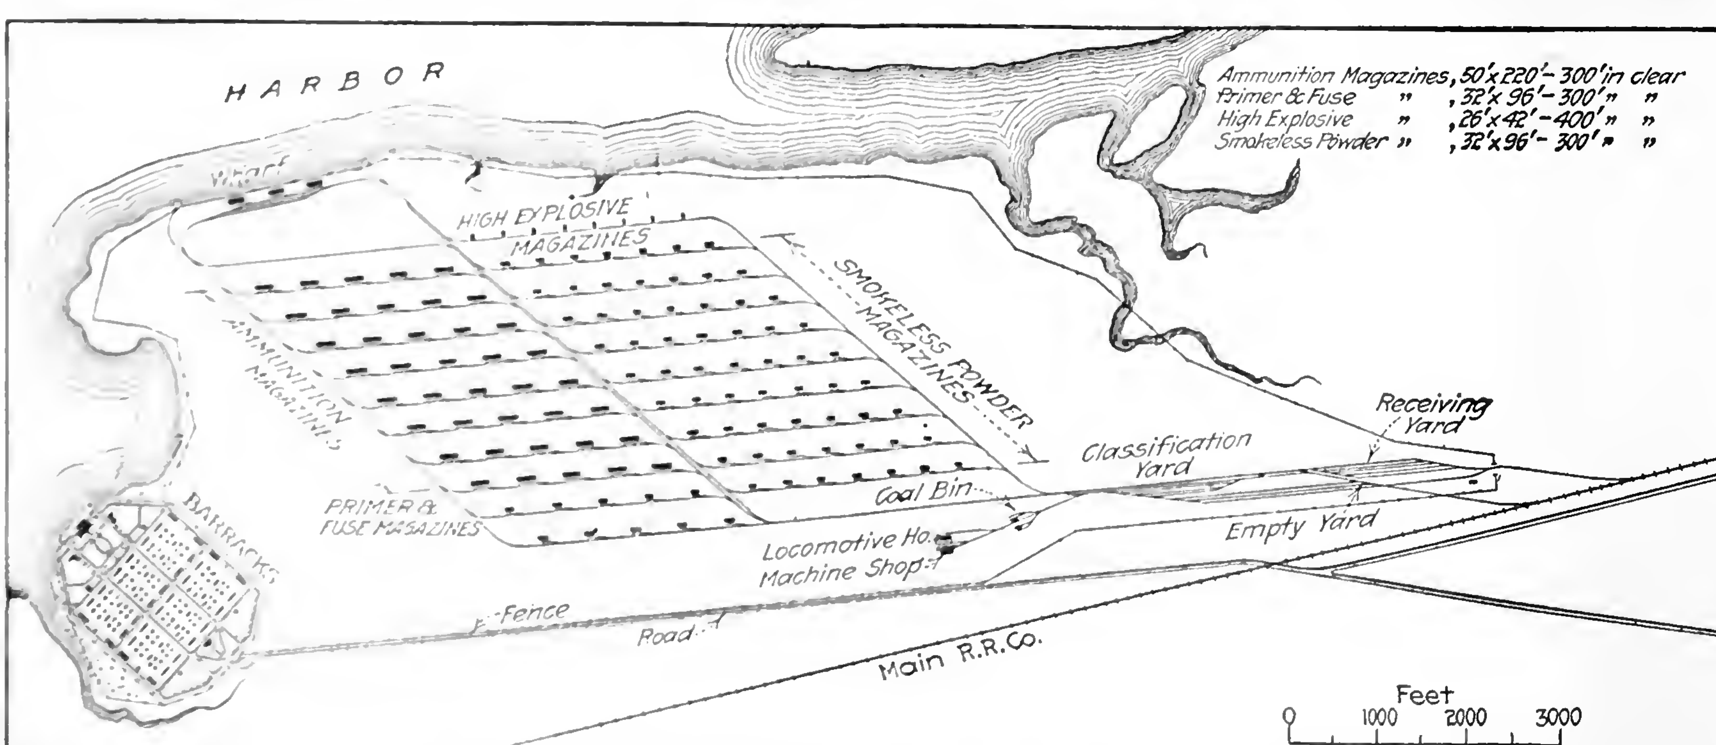
TABLE SHOWING LOCATION AND COST OF ARMY AMMUNITION SEABOARD DEPOTS.

Depot	Harbor	Cost
Raritan Arsenal, New Jersey	New York	$14,883,000
Sandy Hook Ordnance Depot, New Jersey	New York	972,000
Delaware Ordnance Depot, New Jersey	Philadelphia	6,350,000
Curtis Bay Ordnance Depot, Maryland	Baltimore	8,253,000
Turner Ordnance Depot, Maryland	Baltimore	93,000
Pig Point Ordnance Depot, Virginia	Hampton Roads	3,340,000
Charleston Ordnance Depot, South Carolina	Charleston	5,516,000
Total Cost		$39,407,000

As a result of the study of various explosions of ammunition in storage it was concluded that, as in the event of an explosion in any ammunition magazine the shells might be hurled for a distance of one-half mile, it would therefore be necessary to space the magazines that distance apart, to preclude the danger of a bursting shell being hurled from one magazine into the next one and there causing a second explosion. This was obviously impossible, as it would have entailed the construction of tremendous amounts of railroad track and would have required the acquisition of much larger areas of land than could possibly be obtained in the neighborhood of our principal seaports. Experience indicated that a spacing of 50 ft. between magazines would be sufficient to preclude the danger of sympathetic detonation between magazines. It was necessary, therefore, to choose between the above two limits, and a spacing of 300 ft. in the clear between magazines was finally decided upon. The standard layout adopted was to stagger alternate rows of magazines, as this resulted in a slight economy in land.

In planning storage for high explosives in bulk, it was decided that a maximum amount of 250,000 lb. of high explosives per building would not be exceeded. The size adopted as a standard was 24 x 40 ft. by 9 ft. high.

The proper spacing of high-explosives magazines one from the other, and the distances that should be maintained between magazines and inhabited dwellings, railroads, highways, etc., were carefully studied. It was decided to comply with the requirements of the American table of distances regarding inhabited dwellings, public highways and railways outside of the ordnance depots. This table was a result of the studies of a

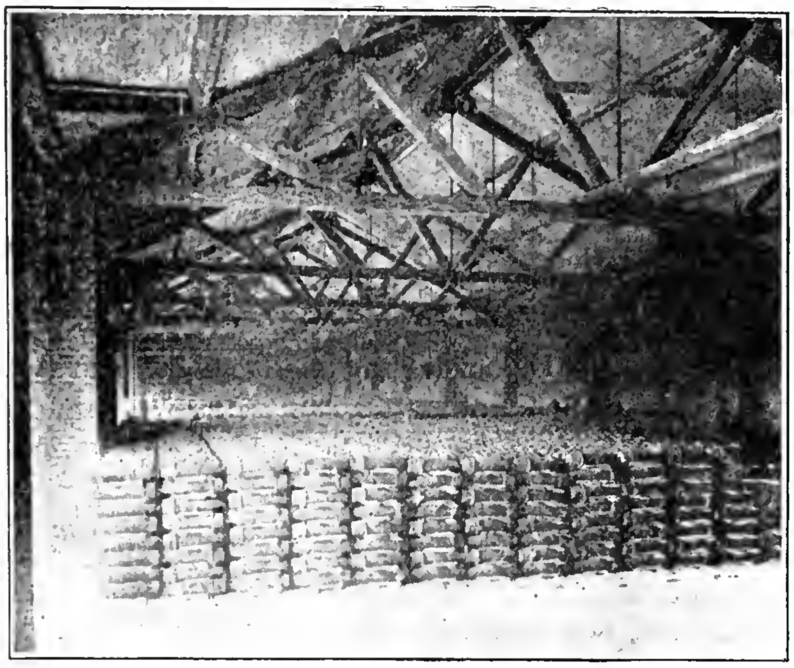


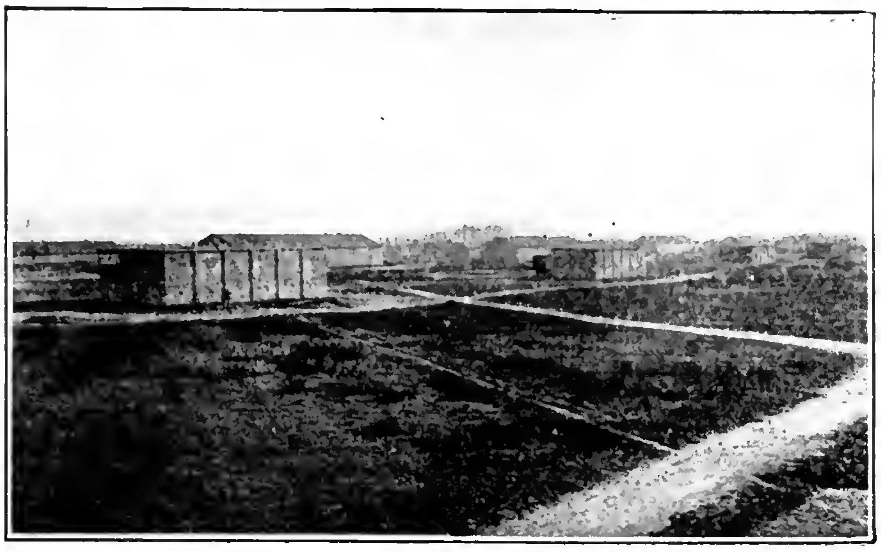
GENERAL LAYOUT OF A TYPICAL ORDNANCE DEPOT, USED AS AN OVERSEAS AMMUNITION-SHIPMENT POINT DURING THE WAR

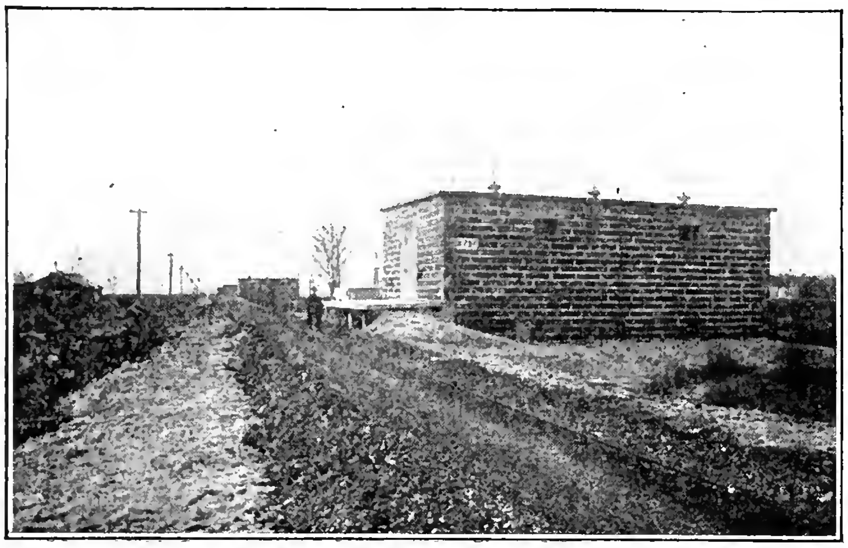
special committee appointed by an association of manufacturers of powder and high explosives established in 1910 and revised in 1914.

A model law for regulating the storage of explosives recommended to various states by the Institution of Makers of Explosives contained a clause regulating the distance between magazines as follows: For 25,000 lb., the spacing between barricaded magazines should be 100 ft. and for each additional 1000 lb. of explosives there should be added a distance of 1⅓ ft., and for magazines without barricades the above spacings should be doubled. According to this rule the barricaded distance between magazines containing 250,000 lb. would be 400 ft. and after consultations with various experts on explosives, it was decided that on account of the relative insensibility of the principal military explosives, T.N.T. and picric acid, as compared with the demolition explosives for which the above rules were made, it was proper under war conditions to store the military explosives in unbarricaded magazines at the barricaded distances described above. This was finally adopted as a standard for the supply division, and all high-explosives magazines of 250,000-lb. capacity were spaced 400 ft. apart in the clear, unbarricaded.

It was decided that smokeless powder should be handled through the ordnance depots in bulk for the reloading of 75s and 4.7s overseas, and loaded in bags for propelling charges for the shells of larger calibers, the bags being packed in fiber or metal containers, those of the latter type being more bulky and more dangerous because each bag contained a core of black powder to assist in the rapid combustion of the charge. A practical test made with several boxes of smokeless powder demonstrated that this material in bulk burns very rapidly but does not explode. It was, therefore, decided that the maximum amount of smokeless powder in bulk to be stored in one building should be 500,000 lb. Allowing for proper ventilation around the walls and for the necessary aisle space, this amount of smokeless powder required a building 32 x 96 ft. by 10 ft. high, which was adopted as the standard-size smokeless-powder magazine.







TYPICAL POWDER AND AMMUNITION MAGAZINES USED BY ARMY DURING WAR IN PORT DEPOTS

Upper left, smokeless powder magazines in group. Upper right, interior of ammunition magazine. Lower left, primer and fuse magazines. Lower right, high explosives magazine

Studies of fires in smokeless-powder factories showed that the flame from a conflagration of a large amount of smokeless powder would reach great distances. It was decided to space the smokeless-powder magazines 300 ft. apart in the clear, as experience available indicated that this would be sufficient to prevent a conflagration in one building from spreading to the adjoining buildings. The spacing adopted is clearly shown in the view of this type.

After the signing of the armistice a revision was made of all high-explosives magazines at the depots established on the Atlantic seaboard, and it was decided that, as a peace-time basis for storage of explosives, the amount of high explosives per magazine should be reduced so that the distance between them would be in strict compliance with the rule described above for the spacing of high-explosives magazines. For the storage of large amounts of surplus high explosives that were on

hand at manufacturing plants, loading plants, etc., new depots were established in sparsely settled areas in the interior of this country. The amount of explosives in them was limited to 250,000 lb. per magazine, and magazines were spaced 800 ft. apart, which is the unbarricaded distance in accordance with the rule referred to above.

In planning the fire protection for the ammunition depots, consultations were held with the manufacturers of explosives, with other experts on the subject, and with the National Board of Fire Underwriters. As a result of this a standard policy of fire protection was adopted and followed at all of these depots. The problem of fire protection was devided into two classes, the first being the protection of the ammunition-storage areas, and the second being the protection of barracks, general storage warehouses, wharves and railroad yards.

Sprinklers Not Warranted

The question of providing the magazine area with hydrants and equipping the magazines with sprinkler systems was discussed informally with the representative of the National Board of Fire Underwriters and with manufacturers of explosives. After thorough study of the matter, it was decided that the great expense of installing a water system through the magazine areas was not justified. If the small fire equipment which it was planned to place at all magazines was not effective in putting out a fire in its incipiency, it was felt that it would then be too late for the sprinkler system to act or for the fire company of the depot to obtain water from a hydrant system scattered through the magazine area. In order to determine whether this decision to omit sprinkler systems from all magazines was justified, arrangements were made at the suggestion of the National Board of Fire Underwriters and through the courtesy of E. I. du Pont de Nemours & Co. to make tests at Carney's Point to determine the value of a sprinkler equipment in fires in the storage of smokeless powder, T.N.T. and picric acid under different conditions. It was the consensus of opinion after these tests were made and studied that the cost of a sprinkler system was not warranted.

It was endeavored to prevent the occurrence of fires in the magazine area by precautions in the construction of the magazines, in guarding, in clearing the magazine area of all fire hazards, and in equipping the locomotives with fire equipment, spark arresters, and specially inclosed ashpans, in order to reduce as far as possible the danger of fire from these sources.

The magazines were protected from fire by a liberal supply of small fire equipment, both inside and outside. The type of small equipment generally used was 40-gal. bucket tanks and 5-gal. hand-pump extinguishers, both being filled with nonfreezing solutions. The fire protection for the barracks was the standard type developed by the Army and used at all cantonments Other important features of the fire protection of the depots were the organization of fire brigades, the establishment of a fire-engine house with facilities for housing the fire marshal and his crew, the installation of electric fire-alarm systems, a liberal installation of telephones, and the construction of numerous small guard houses for housing the detachments assigned to guard duty.

In the design of the ammunition magazines it was attempted to reduce to a minimum the danger from missiles in the event of an explosion; to make the magazines as nearly fireproof as possible; and to make the buildings dry and well adapted to the mechanical handling methods that had been decided on. The standard adopted was a building 50 x 218 ft., with brick pilasters, tile walls, concrete floors and roof of gypsum slabs resting on wood roof trusses and wood purlins. The walls should eventually be plastered on the outside, but this was omitted for the sake of speed and economy. This construction is shown in the views.

Three types of high-explosives magazines were adopted. The type adopted when it was anticipated that they could be used permanently by the Army was very similar to that described above for ammunition magazines and shown in one of the views. The floors, however, were of wood, to avoid danger from striking sparks.

For temporary use, a wood-frame magazine with corrugated asbestos sheathing and gypsum slab roof was used; and for storing dynamite, which material could be detonated by a rifle bullet, bullet-proof magazines were constructed. These latter were similar to those of the permanent type except that the tile was filled with sand and the fire doors were bullet-proofed with steel. A test made with an Army rifle, by firing three bullets at the same spot of a sand-filled tile, resulted in penetrating only the outside shell of the tile.

Smokeless-powder magazines were built of wood frame, corrugated asbestos sides, gypsum roof and wood floors, care being taken not to have any exposed nail heads. One of these is also shown.

Special magazines were built for the storage of primers and fuses. On account of the great cost and importance of these materials, the magazines were made of fire-resisting exterior, the size and spacing being the same as for the smokeless-powder magazines (32 x 96 ft., and spaced 300 ft. apart). The walls of these magazines were of tile, the roof was of gypsum, and the floor of blind-nailed wood plank.

Transportation Methods Important

It was planned to transport ammunition from the magazines to the wharves on flat-cars covered with tarpaulins and to transport explosives in box cars. For the rapid transfer of this material to lighters a front track was built as close to the pierhead line as possible, and light shells and explosives were skidded on hardwood skids direct from the cars to the lighters. For the transfer of heavy shells 15-ton locomotive cranes with 50-ft. booms were provided. These cranes operated on the front track, the flat-cars with shells being spotted on a second track spaced 18 ft. c. to c. from the front track. This spacing gave ample width for the operation of the crane. The standard width of wharf adopted was 46 ft., which left sufficient width in the rear of the second track to permit a fire engine or automobile to pass when the tracks were blocked with railroad equipment. The top of the rail of the front tracks was flush with the floor level, in order to permit of trucking across the tracks when necessary.

The wharves were designed for a live load of 500 lb. per square foot, and the tracks for either a Cooper E-40 locomotive or a 15-ton crane with loaded boom at point of overturning, the boom being so placed as to produce the maximum loads. All bracing was kept at least 3 ft. above mean low water, in order to avoid the delay usually encountered when placing bracing near low-tide level.

Dock sheds of fire-resisting construction, 60 x 216 ft., and spaced approximately 300 ft. apart in the clear, were built directly in the rear of the wharf, and were used as transfer sheds are used on commercial wharves. The floors of these buildings were of reinforced concrete supported on wooden piles and were designed to carry a live load of 600 lb. per square foot. Depressed tracks were built in the rear of the dock sheds to facilitate the rapid unloading of cars into these buildings, and behind these loading tracks small yards were provided to assist in the quick shifting of cars at the wharves.

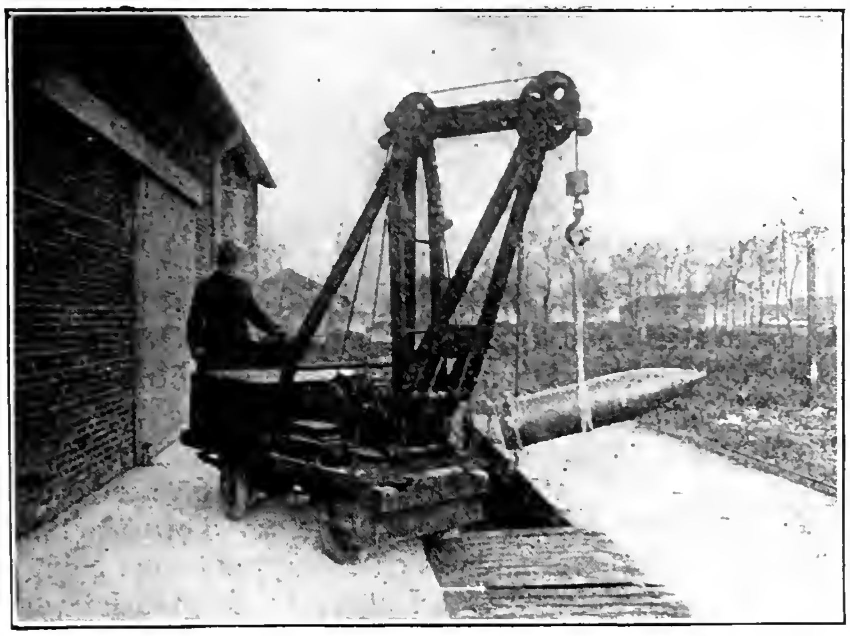
Fire walls were built under all of the ordnance wharves, concrete walls being spaced approximately 510 ft. apart. with intervening timber fire walls constructed of two layers of 2-in. plank, one layer being placed vertically and the other horizontally, and spaced approximately 170 ft. apart.

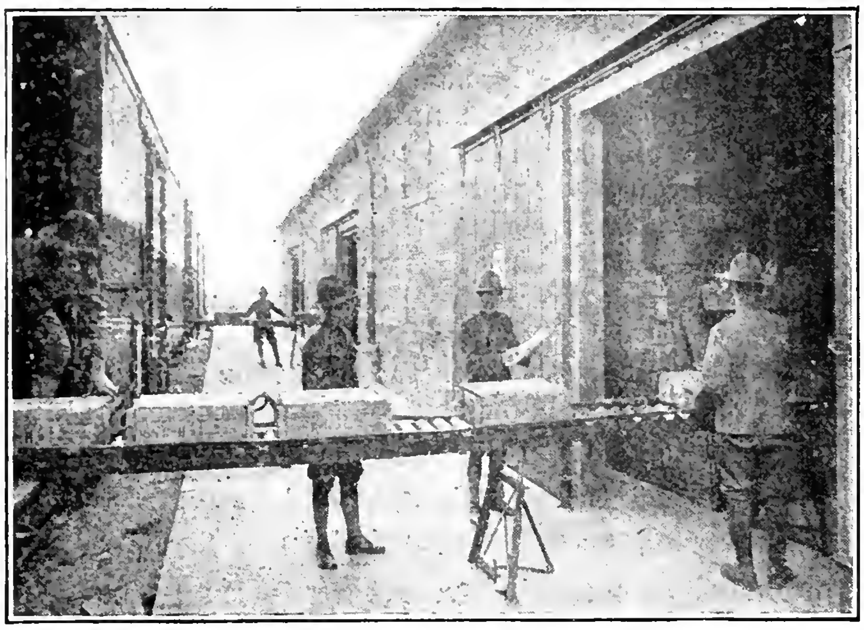
The plan for the pier at Pig Point, Norfolk, Va., differed slightly from the above plan; it was built 4000 ft. from the shore, and it was not anticipated that very heavy shipments would be made from this point. The pier was therefore built 105 ft. wide with a dock shed 260 x 40 ft. with surface tracks on one side and depressed tracks on the other, both sides of the pier being provided with fender piles so that lighters could be loaded on both sides when desired. As a certain amount of vibration was inevitable on this pier, the dock shed was built of wood-frame construction covered with corrugated asbestos.

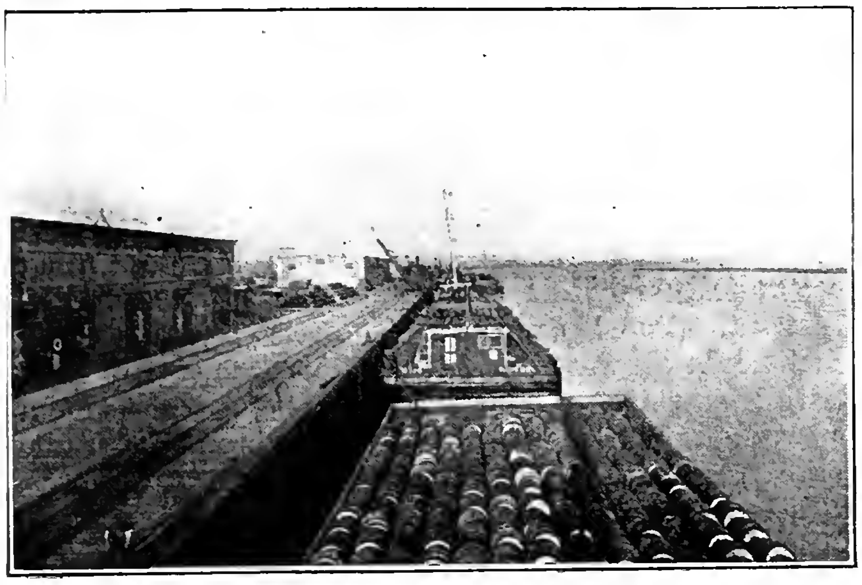
A railroad system was constructed at each depot to make access easy to any point and to provide receiving and classification yards for incoming and outgoing cars. The main running tracks and yards were placed at a safe distance from the magazines. Curvature of track was limited wherever possible to 13°, to preclude any trouble from derailments. The 80-lb. A.S.C.E. rail was selected as a standard for ordnance depots, but, on account of the difficulty of obtaining these rails quickly, a good deal of 67½-lb. rail, which had been manufactured for the Imperial Russian Government but had not been shipped, was used, and proved very satisfactory.

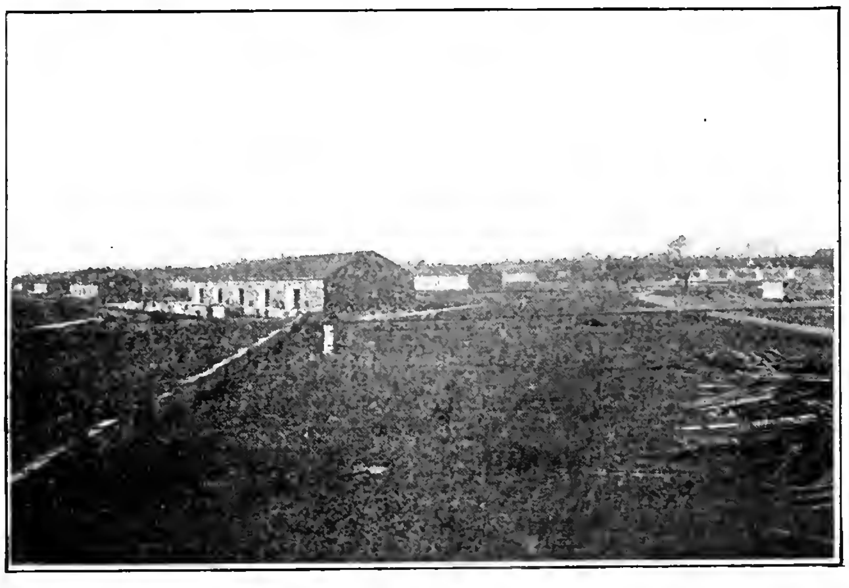
All ammunition depots were surrounded by high fences built of 2-in. chain-mesh woven wire fence of No. 9 galvanized wire surmounted by three strands of barbed wire on an inclined arm, the total height of the fence being 8 ft. To assist in the guarding of the depots a series of flood lights, spaced approximately 500 ft. apart, were installed, mounted above the fence and throwing powerful beams of light parallel to the fence, thus thoroughly lighting a zone approximately 100 ft. wide outside the depots. That the guards inside of the fence might remain in darkness so that they could not be seen from the outside, vertical veins were fastened to the projectors; these reflected all rays directed toward the inside of the inclosure. The projectors were generally spaced 500 ft. apart.

Very careful consideration was given to the use of electrically driven machinery for handling ammunition and explosives in the magazines, but it was decided that any economies that might be gained by the use of this









MECHANICAL METHODS USED IN HANDLING AMMUNITION IN ARMY'S STORAGE DEPOTS
Upper left, electric crane handling heavy shell. Upper right, shrapnel on roller conveyor. Lower left, handling ammunition to barges. Lower right, roller conveyors between magazines

machinery were more than offset by the added risk entailed in running power lines into the magazines. It was, therefore, decided that for powder and high explosives no electrical machinery would be used, and for shells the use of power-driven machinery would be confined strictly to storage-battery equipment, and that the charging of all storage batteries would be carried on in a building outside of the magazine area. Battery-charging stations at safe distances from the magazines were therefore established at all of the principal depots.

On account of the short winter days, and as it was desired to be prepared to handle shipments day and night when necessary, it was essential to provide a means of lighting the magazines. This was accomplished by the use of storage-battery portable lamps, developed for this purpose. These lights were charged at the battery-charging station and could be carried to any magazine where night operations were under way.

Preliminary estimates showed that the trackage at the various depots would average from 10 miles at the small depots to 45 miles at the larger ones, and that the number of carloads passing through each depot would average from 15 to 243 per day. With these facts in mind, studies were made of various types of motive power, including electric locomotives, compressed air, fireless locomotives and oil burners; but there were certain objections to the use of all of these types under war conditions, and it was therefore decided to use for all heavy switching 62½-ton coal-burning steam locomotives, and for light work 40-ton locomotives. The principal reasons for this decision were that electrical equipment was scarce and the large trackage at the depots would have made electric installations very expensive; compressed-air and fireless locomotives were not powerful enough for the heavy work anticipated, and a steady supply of fuel oil could not be counted on at all of the depots. All locomotives were fitted with special inclosed ashpans and spark arresters. The standard locomotive crane adopted for handling heavy shells at the wharves was a 15-ton, eight-wheel, coal-burning crane with a 50-ft. boom.

All of the rolling stock for the operation of the depots was ordered at the commencement of the projects and was used to great advantage by the construction forces.

Roller Conveyors Used

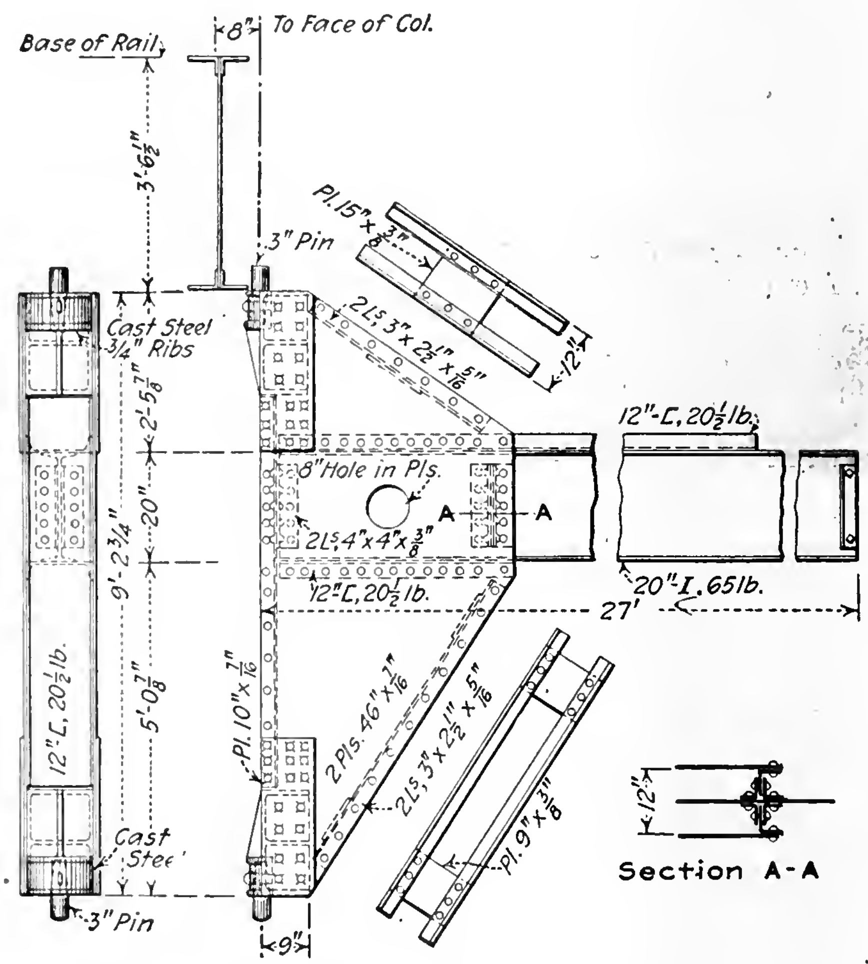
For handling material from cars into magazines, roller conveyors were utilized as far as possible. For inert material and shell, the ordinary steel roller conveyor, made up in 8-ft. sections, was used. Various forms of wooden pallets were provided for moving articles such as shells, bags of sodium nitrate, etc., over the conveyor. For handling explosives such as T.N.T., dynamite and black powder, wood roller conveyors fitted with wood guard rails were used to avoid the risk of sparks.

For handling shell above 12 in. in diameter a special type of storage-battery transfer crane truck, fitted with a short hinged boom and a hoist motor, was provided. As the platforms of the magazines used for the storage of heavy shells were built at car-floor level, this truck could be driven into the car, take a shell either by the nose ring or by means of a rope sling, back out of the car and proceed head on into the magazine to the point of storage. A view is given of one of these cranes in operation.

Jib Crane Designed for Maximum Clearance

TO REDUCE the overhead height of jib cranes recently installed in the Carnegie warehouse of the McClintic-Marshall Steel Supply Co. and thereby give maximum underclearance and lifting height, a special design was developed, using, instead of tension stays to take the cantilever moment, what was virtually a vertical girder. The details of this design are reproduced herewith.

The vertical girder was built up of two main plates with a 12-in. channel on the side near the column, and



SPECIAL DETAILS OF CANTILEVER JIB CRANE

with angle stiffeners and tie plates supporting the edges. The main cantilever beam was framed into the vertical channel just mentioned, and was also connected by four vertical angles through the main plate, as indicated by section AA. Horizontal 12-in. channels were selected to connect the flanges to the main plate, as shown in the drawing, one of these channels on the upper flange being extended for a distance of about 18 ft. to give lateral stiffness to the cantilever beam. An 8-in. hole in the main plate was necessary in order to allow access to the rivets on the inside of the box section.

The bearings are of cast steel, using in general a thickness of ¾ in. for the ribs and main metal. The design was made by P. L. Wolfel, chief engineer, McClintic-Marshall Co., Pittsburgh, Penn.

Publicity To Help Minnesota Water Projects

An educational campaign to assist municipalities which need new water-supplies or improvements in their existing supplies is a new activity being carried out under H. A. Whitaker, director of the Minnesota State Board of Health. The program includes a thorough investigation and report, also conferences with local officials and organizations, and lectures at public gatherings, in order that the people may have an opportunity to realize the importance of the problem before the time arrives for voting the necessary funds.

Long Concrete Bridge Contract To Be Let in Four Parts

Structure Nearly Mile Long Across Mohawk River and Barge Canal at Schenectady About To Be Built

JUST before the United States entered the war the State Engineer of New York had prepared plans for a long, reinforced-concrete bridge across the New York State Barge Canal and the Mohawk River between Schenectady and Scotia, N. Y. The work was held up during the war, but appropriation has now been approved by the legislature and preliminary work incident to the award of contracts will be begun immediately.

GREAT WESTERN GATEWAY, A CONCRETE BRIDGE NEARLY A MILE LONG, TO BE BUILT AT SCHENECTADY, N. Y.

In addition to the size of the structure, it is interesting on account of the novel division of labor proposed for the construction. Under a plan now in preparation, the first contract to be awarded will involve the construction of the approaches and abutments at either end of the bridge. The second contract will involve the excavation, the driving of foundation piles, the placing of concrete in the foundation of all the piers and abutments exclusive of the end abutments. This contract can be awarded at practically the same time as the first one, inasmuch as the two contractors can operate without any material interference. As this second contract will be composed almost exclusively of work in which contractors experienced in the building of foundations and the driving of piles would be interested, it is thought that keen competition will result. The third contract consists of placing concrete above the foundation lines, including arches and balustrades in the main portion of the structure, and the fourth in the pavement of the bridge and approaches. This fourth will be the last part of the work to be placed under contract. Under this scheme the first and second contracts would be practically completed through the 1919 season, and in 1920 the third contract would be awarded; the work would be completed toward the end of 1921.

The bridge is to be called the Great Western Gateway or Gateway Bridge. It has a total length of 4436 ft. comprising 23 spans varying from 106 ft. to 120 ft., and one 212-ft. span over the Barge Canal channel. The river at the site is divided into three channels by Van Slyck Island and Hog Island. Between Van Slyck Island and the Schenectady shore is the channel which leads up to the Schenectady Barge Canal terminal. Between the islands is the Barge Canal channel, and between Hog Island and Scotia is the river.

Starting at Washington Ave., Schenectady, as the continuation of State St., the main artery of east and west traffic through the city, the first 300 ft. of the structure to the Schenectady abutment will be in the form of a parkway 100 ft. wide between retaining walls. In the center of this will be a grassed reservation 20 ft. wide for street-railway tracks, and flanking this will be reservation roadways, 20 ft. wide, for vehicular traffic. Flanking the roadways will be grassed areas 10 ft. wide and then outside concrete sidewalks 10 ft. wide. From the Schenectady abutment to the Scotia abutment the roadway will be 40 ft. between curves, with double tracks for electric cars in the center, and two 6-ft. sidewalks. Four arch spans 106 ft. each, cross the terminal channel to the triangular pier on Van Slyck Island, where the bridge turns at an angle of 54°. The crossing of Van Slyck Island is in three arch spans 110 ft. each, one arch span 117 ft., all square-ended, and four arch spans 120 ft. each on a skew of 18°. Then comes the 212-ft. span across the Barge Canal, which is on a skew, then six 120-ft. skew spans, an anchor pier on the far side of Hog Island, and five more skew spans of 120 ft. each. The structure between abutments is divided into five sections by two anchor piers and the massive piers of the channel span.

All arches will be open spandrel, rib type. The 212-ft. span will be carried on two ribs 12 ft. wide, 24 ft. apart. All other spans will be carried on three ribs, the outer ribs 6 ft. wide and the center rib 12 ft. wide, with a clear distance between ribs of 12 ft. On the Scotia end, for a distance of 940 ft., the approach will consist of an earth embankment.

The new structure will replace the old steel toll bridge which crosses the river about 1200 ft. to the east. It will be paid for jointly by the State of New York, the City of Schenectady, the County of Schenectady and the Village of Scotia. The contract plans were prepared by Frank M. Williams, state engineer, from the original design by B. H. Davis, consulting engineer.

Good Results From Filter Galleries

Bacterial count of the water obtained in 1918 from the underground galleries of the Des Moines, Iowa, Water Works Co., which are flooded at times of low river stages and high consumption, indicated a 94.5% reduction from the average of 19,047 bacteria per cubic centimeter in the adjacent Raccoon River. Treatment with chlorine gas reduces this count to 48, according to a paper read at the recent meeting of the Iowa Section of the American Water Works Association by A. T. Luce, engineer and superintendent. The rate of infiltration from a series of ditches and pools extending along the land side of the galleries is estimated at 1,000,000 gal. daily per acre flooded.

Continuous Trains for Forty-Second Street Transit

Problems of Dense Traffic—Moving Platforms or Continuous Train Recommended for New York Ten Years Ago—Shown to Have Advantages in Speed up to Four Miles, and Remarkable Capacity

By Henry B. Seaman

Consulting Engineer, New York City; Former Chief Engineer of the Public Service Commission for the First District, New York

A RAPID-TRANSIT problem of peculiar importance is contained in the case of the 42nd St. shuttle-train service in the new subway system of New York City. The problem is that of short-distance transfer of a very dense traffic, and is by no means confined to New York City or to the 42nd St. connection. But the latter is of such immediate urgency as to require serious study at the present moment. It is the writer's conviction that the moving platform, or the continuous-train system, offers the only solution of this problem. Moreover, the same system is able to meet requirements of exceedingly dense rapid-transit traffic in other cases, for long as well as short distances. In the present period of active rapid-transit development, the subject merits general attention.

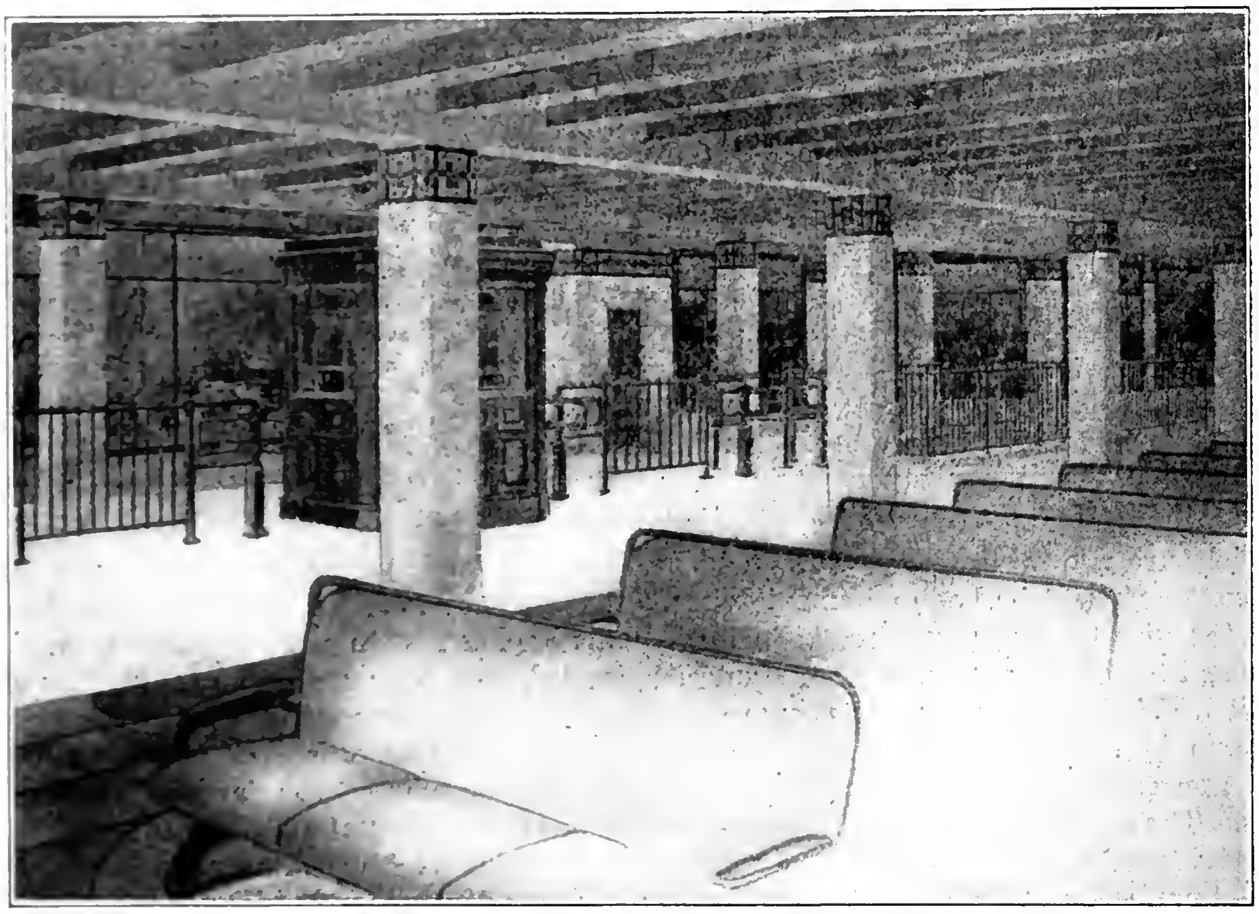


FIG. 1. HOW A MOVING PLATFORM SUBWAY INSTALLATION WOULD APPEAR, WHEN VIEWED FROM THE CENTER LINE OF COLUMNS (SLOW SPEED APPROACH PLATFORMS BEYOND THE SEAT PLATFORMS)

Ten years ago, when chief engineer to the Public Service Commission of New York City, the writer reported to the commission that moving platforms offered distinct advantages over separate trains with respect to speed as well as to capacity, recommended that an installation be made forwith. The general facts set forth in that report are as fully applicable today as then, and reference to them will support the statement that other rapid-transit routes than the 42nd St. shuttle connection may advantageously be equipped with continuous trains.

When the original subway, running north and south in Manhattan, was built, it was laid out on an indirect route through 42nd St., in order to reach the most populous localities and thus insure the immediate financial success of the project. But it was evidently intend eventually to complete the east- and west-side routes as now constructed. It would, therefore, seem that the connecting link across 42nd St. should have been considered and designed at the same time, in order to function with this general subway development. That this was not done can only be explained by the extraordinary pressure to rush the general improvement.

When, upon the opening of the new subways, it was found that no consideration had been given to this important matter, and it became necessary to close down the crosstown service in 42nd St. temporarily in order to avoid the resulting confusion, the citizens were naturally surprised and expressed disappointment. At the suggestion of the chairman of the commission, colored guide lines were then introduced. This was expected to reduce confusion, and the shuttle service was reëstablished. Other than this, however, there have apparently been no serious attempts to provide permanent relief of the congestion and inconvenience at this point.

A suggestion has recently been made by a former member of the commission that the shuttle service be operated from 14th St., running trains on the local tracks of the main line to 42nd St. and thence across to Seventh Ave. As a considerable portion of the crosstown traffic comes from the Steinway tunnel on the east and an ever-increasing number from the Lexington Ave. extension on the north, such operation would offer, at best, only partial relief.

Furthermore, in order to introduce a shuttle service which would be even approximately satisfactory, it would be necessary to switch at least half the local trains from 14th St. on the main line to the shuttle service across 42nd St. Since the interval between trains on the main line is about 2½ min. during rush hours, it would reduce the service on both the shuttle and the Lexington Ave. main line (above 42nd St.) to 5-min. headway, which would be entirely unsatisfactory in either case. Rush-hour service on all lines should approach 2-min. intervals as closely as practicable.

An alternative would be to deflect half the local trains on the lower east-side line across 42nd St. and then northward on the west-side line, and in turn deflect a corresponding number of trains from the lower west-side line across 42nd St., and thence northward

on the east-side line. This would form a balanced system of operation, and would come nearer to fulfilling the requirements than any other train service which could be proposed, though the shuttle service would still be restricted to 5-min. intervals. In order, however, to make the necessary connections from the lower west-side to the upper east-side line, these plans should have been included in those of the general improvement—if, indeed, they could have been made at all. Now, with the general development which has since taken place, notably the completion of the Hotel Commodore, such connections cannot be made except at prohibitive cost.

The next possibility is utilizing the Steinway tunnel for relief by extending it westward to Seventh Ave. Plans for such extension were considered years ago, and undoubtedly such construction is still possible. But these plans were merely for the convenience of the traffic from Long Island City, and were not intended to fill the purposes of the present shuttle service. The tunnel is too deep for the purpose, and is difficult of access from the street surface.

At Lexington Ave., and again at Seventh Ave., the Steinway tunnel extension must pass below all other subways. It could approach the surface only somewhere midway between these two points; that is, in the vicinity of Fifth Ave. and 42nd St. But here street traffic is already so congested that a further increase is undesirable. Plans for a revision of street grades at Fifth Ave. have been under consideration.

An expenditure of possibly $3,500,000 would be required to construct the Steinway tunnel extension. The present subway section in 42nd St. would be of little value unless use could be made of it as an auxiliary. Some three years were required to construct the 42nd St. subway, and it could hardly be expected that the more difficult Steinway tunnel extension would be built in less time.

Moving Platform Operation

With these three suggestions of train service eliminated, the remaining expedient is the introduction of the moving platform, or a similar device, in the subway as at present existing.

While the introduction of this method of transportation would be novel and would call for the greatest structural and mechanical engineering skill, the system has been investigated by the most eminent engineers of their day and has received their unqualified indorsement. It is the escalator principle of continuous service, applied to horizontal transportation. To object now on the score of its novelty is not "conservative," but rather unprogressive and unscientific. The work should be undertaken, however, only by men of clear vision and of strong mechanical instinct, men who are determined to succeed and who are capable of overcoming obstacles as they appear.

The introduction of the moving platform into the present subway in 42nd St. would save the bulk of the expense of the Steinway tunnel extension. The cost to the city would be nominal. Close connections could be made with the Interborough subways which it is intended to serve, as well as with other subways, if so desired.

In its operation there would be no intervals of waiting between trains, as with car service, since the platform is ever there and ever moving. The traffic level would be nearer the street surface. Entrances and exits could be provided at every street, or, indeed, at every store. Finally, the equipment may be so designed that when it is in full operation and has demonstrated its efficiency it may be extended through the Steinway tunnel, affording continuous passage from Long Island City.

Studies of the moving platform or continuous-train system, made for the purposes of the report to the Public Service Commission in 1909, already referred to, brought to light very significant facts concerning the transportation value of the system. In point of capacity it surpasses the highest demands of present-day

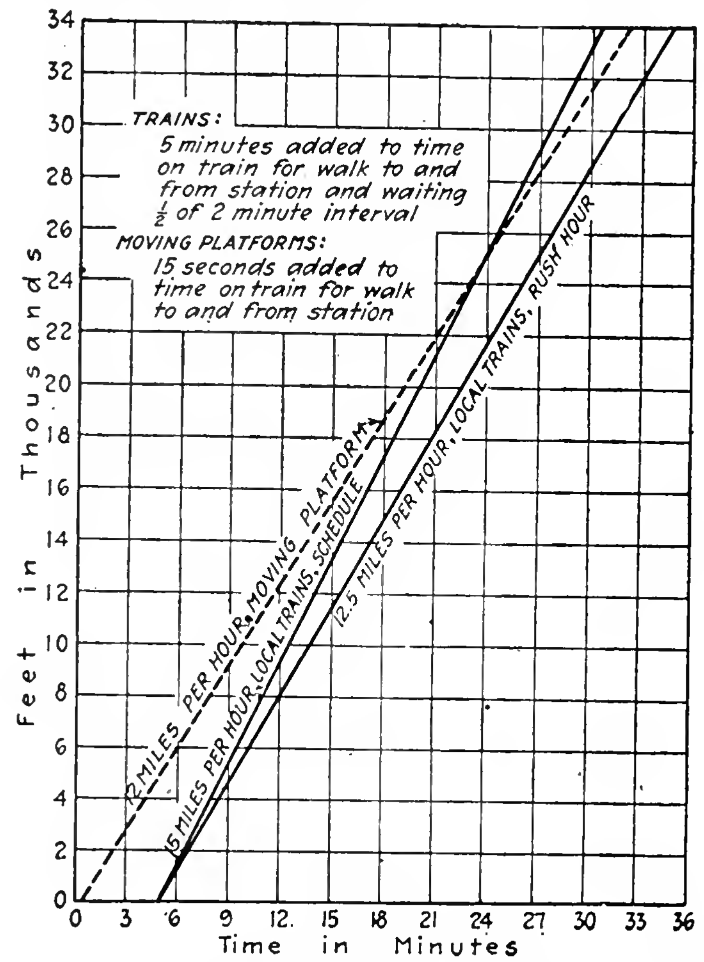

FIG. 2. SPEED COMPARISON OF MOVING PLATFORM AND TRAIN

traffic. In point of speed it has the advantage over the present system for all distances up to four miles.

For the speed calculations, data were taken from rapid-transit service as it existed in New York City, average conditions being selected as follows:

Distance between express stations	2 miles
Distance between local stations	⅓ mile
Distance between cross streets	1/20 mile
Speed of express trains, including stops	25 miles per hour
Speed of local trains, including stops	15 miles per hour
Speed of moving platform	12 miles per hour
Speed of pedestrians	3 miles per hour
Average interval between trains	3 min.

It was assumed that the average passenger starts his journey at a point distant from a local station by one-fourth the spacing of stations, and travels to a point of destination likewise one-fourth the station spacing away from a station. It was assumed that he must wait at the station for a time equal to one-half the interval between trains. These data led to conclusions which are plotted on the diagram, Fig. 2, herewith.

For all distances less than four miles the moving platform is a quicker mode of conveyance than local train service or even local and express service combined. This is true on the assumption of a speed of 15 miles per hour for local trains. But, as a matter of fact, local

service during rush hours averages only about 12 miles per hour, and under these conditions the platform has the advantage over the train for all distances.

Great superiority in passenger capacity is, however, the primary distinction of the moving platform, next to its ability to receive and discharge passengers anywhere along the line. It can carry 73,500 passengers per hour, all seated, against 58,500 passengers for ordinary trains with both express and local service on separate tracks (36,000 for eight-car express trains, 22,500 for five-car locals) of whom only one-third would be seated. Ten years ago the writer reported that "the

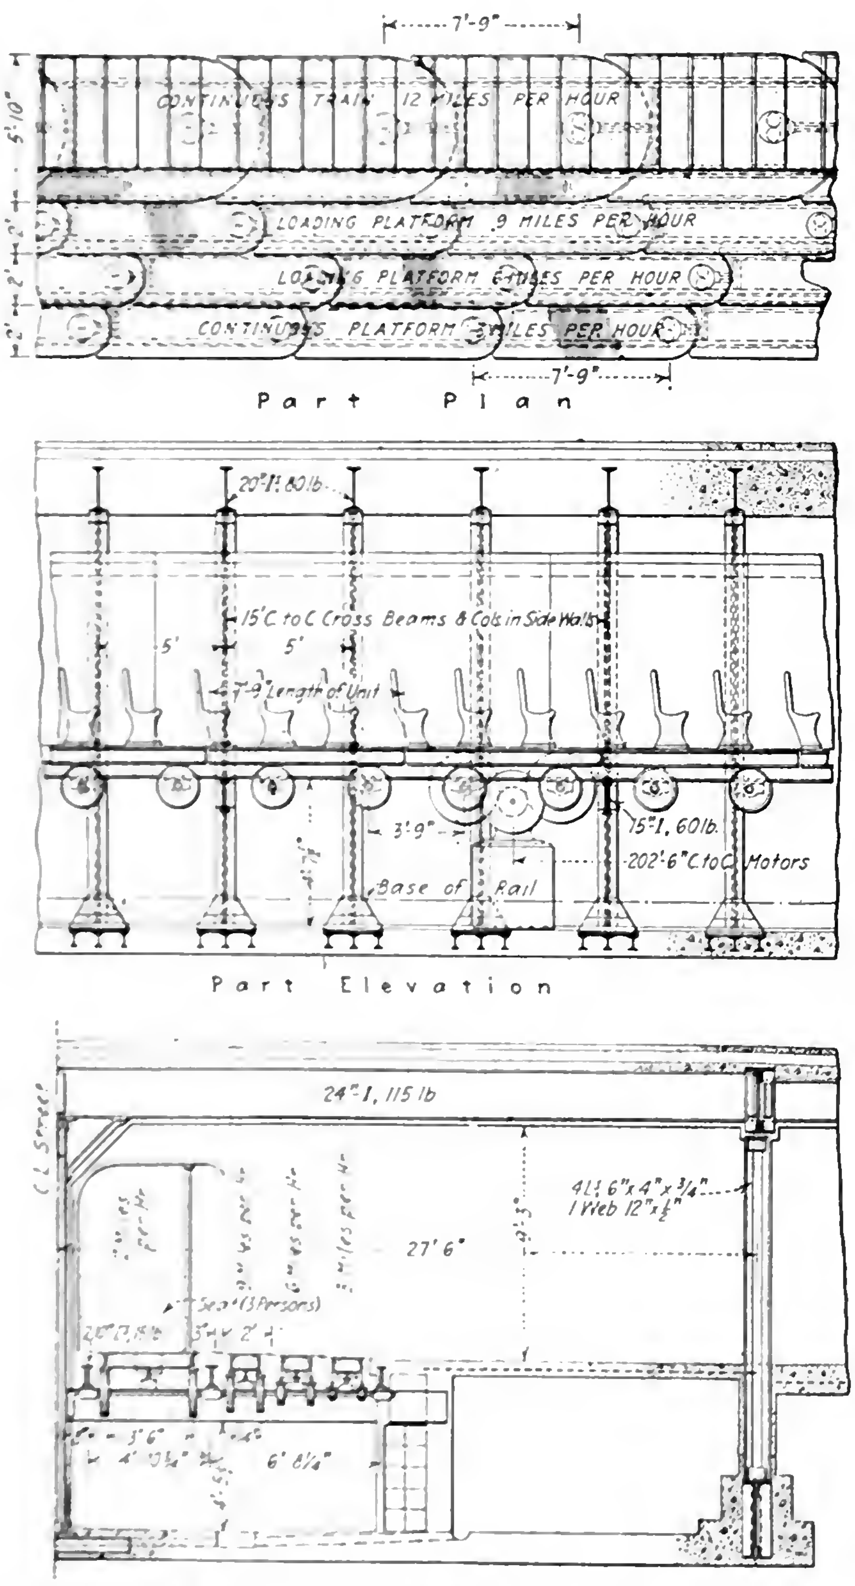

FIG. 3. ADAPTATION OF MOVING PLATFORM TO A SUBWAY DESIGNED FOR TRAIN OPERATION

capacity of the moving platforms is beyond any requirements which can at present be foreseen." Though the density of traffic in the New York subways has more than doubled in the interim, this statement is approximately true even today.

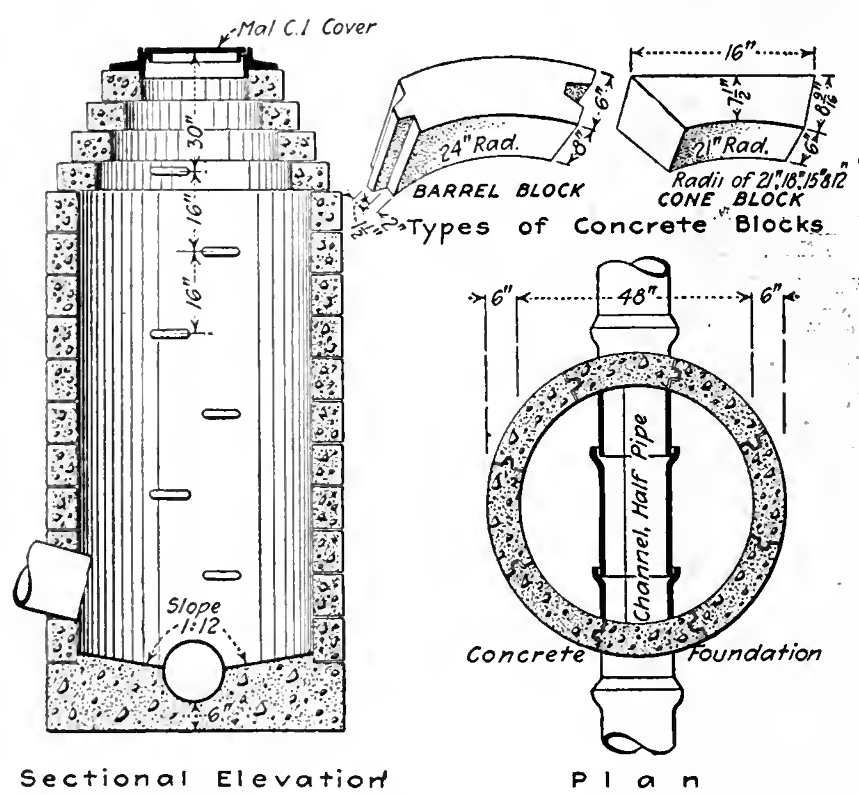
Introduction of the moving platform into the future transit system of New York City is inevitable. The channels of subway construction in lower Manhattan are practically filled, and in the increase of travel which will develop the inadequacy of the present transit facilities to accommodate it will become increasingly evident.

Design and Cost of Concrete-Block Manholes for Pipe Sewers

By R. A. Koerner

City Civil Engineer, Terre Haute, Ind.

CONCRETE-BLOCK manholes for pipe sewers, as built at Terre Haute, Ind., in accordance with the accompanying illustration, cost 40c. each, or about $8 per foot of height. The blocks are made of 1:2:4 concrete, with 10% of hydrated lime added for water-



CONCRETE-BLOCK MANHOLE FOR PIPE SEWERS

proofing. The floor of the manhole is sloped to obviate the remaining of sewage in the manhole when the sewer is running over half full. The same general design is used for catchbasins. So far as known, the design shown is original with the writer, who was led to make it by the exorbitant price demanded for brick.

Salvaging Construction Material in China

A letter from Donald F. McLeod, professor of railway engineering in the Chinese Government Engineering College at Tangshan, North China, describes an interesting adaptation of local materials to construction in hand. The contractor who dug a large, open well on the campus, 30 ft. in diameter and about the same depth, used for cribbing the stalks of a plant similar to sorghum to hold up the sides of the excavation, together with the surcharge due to the material excavated, until he could get a stone lining in place. He successfully salvaged all his sorghum stalks as the stone wall was completed. The letter continues: "Sorghum stalks are valuable as fuel when they are of no further use for building material. Although there are coal mines here the shafts are deep, about 1300 ft., which makes coal cost $4 per ton; pretty high for a man who gets only 30c. a day in wages. Consequently, nothing in the way of vegetation is despised as fuel, every leaf, every blade of grass being carefully gathered up for that purpose."

The title here used is that employed by Mr. Shenehon. Had we rewritten it we would have called the article, "The Philosophy and Romance of the Engineering Activities of the Minnesota Country."—EDITOR.

The Engineering Activities of the Twin Cities

An Address by Francis C. Shenehon, Consulting Engineer, Minneapolis, Before the Forty-Ninth Annual Convention of the American Society of Civil Engineers, Minneapolis, June 17, 1919

IN interpreting this subject "The Engineering Activities of the Twin Cities," it will be assumed that the Twin Cities are simply the hub of a radiating series of engineering activities, that follow transportation lines southward to the Gulf of Mexico, reach northward to the Lake of the Woods, and, loosely defined, eastward and westward to the Gulf of St. Lawrence and the Red River of the North. You will observe that the engineering activities of the Twin Cities are far-flung!

As I proceed to develop my theme, Sherlock Holmes might discover that my interests and convictions are hydraulic, because *water*, whether I will it or not, recurs and resounds like the burden of an opera.

The early voyageurs, Radisson and Groseilliers, who penetrated the wilderness and reached the prairies of Minnesota, and the Mississippi River in the vicinity of Winona, some miles south of St. Paul, started their pioneering journey at Montreal, proceeded by canoe up the Ottawa River to Georgian Bay, Lake Huron, thence to the inlets along the west short of Lake Michigan; and finally made an overland journey of 150 miles westward to the Mississippi. This was about the middle of the 17th century. These voyageurs prepared no maps of this region. Joliet in 1673 reached the Mississippi by way of Lake Michigan and the Illinois River, and opened a water avenue from the south for French exploration of Minnesota. Almost exactly 240 years ago this time of year, Sieur Duluth landed in the vicinity of the present City of Duluth, and penetrated the inland country of Minnesota to Mille Lacs, about 70 miles from Minneapolis—the first white man to report and record his explorations. Later on the Sieur La Salle, and Father Louis Hennepin (in the summer of 1680) came to St. Paul. Hennepin went on to the cataract to which he gave the name of his patron saint, Anthony of Padua. The Dakota Indian name for St. Anthony Falls was Minni-i-ha-ha—"the rushing water"—a name now transferred to the smaller falls immortalized by Longfellow, Minnehaha—"laughing water."

"Exploration Engineers"

These pioneers were *Exploration Engineers*, and their activities have had to do with present engineering activities in the Twin Cities—and they reached here by water transportation in birch-bark canoes. The motives of these exploration engineers, engaged in a reconnaissance survey for the advance of civilization across a continent, were mixed. The inculcation of religion in pagan souls, the extension of imperial domains, fur trading, adventure—and the search for a westerly passage from France to China—all had a part. The naming of the St. Lawrence Rapids at Montreal, Lachine Rapids—or "the Chinese rapids"—illustrates the geographical misapprehension as to the nearness of the Orient, which was actually more than 8000 miles toward the sunset. It is said of Nicollet, "so confident was he of reaching China that he took with him a gorgeous mandarin's robe of damask to wear at his court reception."

This Minnesota country, penetrated by these exploration engineers, was inhabited by savage peoples—Indians—whose chief engineering activities were military—eternal warfare. They subsisted by hunting and fishing perhaps more substantially than by agriculture. Wild rice grew in marginal shallows of the lakes and rivers, wild fowl fed on the wild rice; moose came to the water, as cattle do, to drink, keep cool and avoid fly pests; fish abounded; the streams were avenues of transportation—hence aboriginal populations kept close to the waterways.

Where French and Indian Met

It is rather astonishing how this dependence on lakes and streams is reflected in Indian names, which now exist as geographical permanencies. Minnesota means blue or misty water. The name was first applied to the Minnesota River, and then taken over by the state. Missouri is Dakota for turbid water. Mississippi is Algonquin for far-reaching waters. Minnetonka means Great Water. Minneapolis is a half-breed name—Indian mother, "Minne," waters, Greek father, "polis," city—hence, the City of Waters. These recurring Indian names, and the French names Radisson, Hennepin, Nicollet, La Salle, Joliet, Frontenac and Duluth, still keep vivid the color of two centuries in which the picturesque glories of the French civilization met, by forest and prairie, the ancient, unprogressive, but picturesque, savagery.

My conception of a civil engineer is that he is a surgeon operating upon the earth as his patient; and in developing my subject it appears desirable to touch very lightly, and very briefly, on an activity, essentially engineering, which preceded the Indian and the French in this region. The Panama Canal in some form might ages ago have been cut by geologic action, without the guiding hand of the engineer as we know him. And this surgical operation successfully completed at Panama has done a thing which we find in other places already done for us by sure, slow, constructive geologic forces directed by the Engineer of the Universe. The problems engineers deal with today are inextricably and fundamentally dependent on natural evolutions and physical changes of the past. We take up the task at the point to which Nature has already brought it, and accelerate, retard or modify the project. We are in partnership with every elemental physical force of the universe, and each one of us likes to think of himself as the dominant senior partner.

Geological agencies conferred on Minnesota vast stores of hematite, the blood-red iron ore. Perhaps an account of the genesis of this deposit, the succession of events resulting in making it accessible and commercially worth while, will be of interest, particularly to those who are to visit the Iron Range. About $4\frac{1}{2}\%$

of the crust of the earth is iron; and every stream entering the ocean carries to this omnibus catchment basin a small contribution of this metal. It gradually precipitates in the deep sea bottom, securing oxygen and carbon in part from animal and vegetable organisms, until after countless æons great beds of ore are laid down. Then as the earth cools state-wide slabs of crust are reared above the sea level. A glacier scrapes off and truncates this pyramidal mass. Now, this hematite, as it came out of the sea, was not commercial ore, it was only about 30% iron. But, exposed to the elements, it weathers. The oxygen and carbon in part disappear, while all iron remains, until enrichment is complete, and the ore is commercially good, with 50% or more of iron.

The geological formations exposed in the Mississippi River gorge are interesting in their genesis, and tremendously important to the Twin Cities as bearing on present engineering activities.

Down underneath is the St. Peter sandstone several hundred feet in thickness. This is made up of fine, rounded grains of white sand imperfectly cemented with porcelain clay. This sandstone is so soft that you can carve your initials in it with your finger nail. It is porous and contains in part the artesian reservoir of water. On top of the sandstone are 4 ft. of blue shale, and above this about 30 ft. of limestone; then on top glacial drift, about 30 to 40 ft. of a mixture of sand, gravel, boulders and clay.

The sand was deposited ages ago in the sea, near shore in shallow water; then the bottom of the sea subsided, and in the deeper water the finer sediment, mud with some lime and some organic life, formed shale; the bottom of the sea was then further depressed, and in the deep sea, far from offshore sedimentary deposits, the pure hard limestone formed, imprisoning in its solidifying grip the organic dead. Then the ice sheet, a mile thick over this region, melted and left the rock débris, which we call glacial drift.

Might Have Been No Minneapolis

The significance of these geological formations is shown by the recession of the Falls of St. Anthony from somewhere down in Iowa to its present location in Minneapolis. The destructive force of the falling water successively cut out the soft sandstone, undermining the limestone ledge, toppling it down, and permitting the persistent northward travel of the falls, with the ever-lengthening gorge. If civilization and engineers had been in Minnesota some thousands of years ago, the water-power might have been caught and held at St. Paul, and there would have then been no Minneapolis! Minneapolis itself nearly lost the water-power by northward recession of the falls some forty-odd years ago. But engineers terminated the freedom of geologic action, built a great cut-off wall of concrete to protect the sandstone, and directed the flood waters over a timber apron. The engineeering activities of that day, in this arresting the recession of St. Anthony Falls, makes an interesting chapter in local history. The Mississippi River for sixty miles above Minneapolis has its channel in glacial drift. The high dam in the gorge below is founded on glacial drift mixed with fragments of limestone, while the power house and the vessel lock, at the two ends of the dam, are founded on the sandstone.

The Third Avenue bridge, a monumental recent engineering construction, is founded on the limestone ledge.

The sandstone formation is readily tunnelled, and Minneapolis and St. Paul, in particular, utilize this very fully for sewers.

With this historic and prehistoric background, the story of more recent developments and present engineering activities should be more understandable.

Navigation and City Location

In the days when Minnesota was on the lonely frontier, St. Paul grew to be its most populous city and later its capital, because it was at the head of practicable steamboat navigation—a water reason. Contrary to the rule of growth of cities, which fixes them a day's journey apart, Minneapolis grew into our largest city, centering about the great water-power here—a descent of about 48 ft. in a cataract in the Mississippi River, with over 20,000 available horsepower—another water reason. Another city, Stillwater, grew up at the virtual head of steamboat navigation on the St. Croix River, a tributary stream of the Mississippi, which is the trunk line of navigation leading to the Gulf of Mexico.

In passing, it may be of interest to note that in the division of spoils in state institutions St. Paul received the desirable capitol, Stillwater the desirable penitentiary, and Minneapolis the then doubtful university, all now centers of engineering activities.

Minneapolis and Stillwater had a kinship in the fact that a form of navigation, much exceeding the steamboat in importance, existed in the floating of logs on the upper Mississippi and the upper St. Croix, which, with their many tributaries, found their headwaters in the heart of limitless forests of pine, hemlock and cedar. At Minneapolis the forest products met water power which, with steam power, converted logs into lumber. At Stillwater steam sawmills operated and the logs were also rafted, to continue their journey southward. The floating of logs was the most considerable navigation which the Mississippi River through the State of Minnesota has ever known. It is a familiar fact that a stream which does float logs, and crosses a state boundary, ceases to exist only as a child of the state in which it has its source, but becomes a ward of the Federal Government, subject to all the limitations and advantages which this implies. The transportation of logs and the cutting up of logs in the past have been essential and important engineering activities, which now have practically vanished with the near destruction of the forests.

The water powers at Minneapolis and in the vicinity are the present dominant natural elements, which create engineering activities, which in turn supply other engineering activities. For the future, when population is dense enough, river navigation promises to mean much for Minneapolis, St. Paul, Stillwater and other river cities.

At the present time, by the building of the high dam and lock between Minneapolis and St. Paul, the actual head of navigation for steamboat service on the Mississippi River is brought to Minneapolis. The construction of this vessel lock and dam is one of the fairly recent engineering activities of the Twin Cities. The evolution of the project from a two-lock scheme, which neglected the water power (10,000 horsepower) inevitably present, marks the transition of the Federal Government from the rôle of navigational proprietor

alone, blind to other uses, to the larger rôle of master of navigation and water power both. It is a little discouraging, however, to note that three years, during the war period, when our railways were congested getting coal to this water-power city, much steam-generated power was in use and coal consumed, while potential power equivalent to perhaps 50,000 to 100,000 tons of coal a year was wasted through the sluiceways or over the crest of the dam. The dam itself is of the Ambursen type, with normal 30-ft. head, with power-house foundations built contemplating a use of 6000 cu. ft. per second in generous river stages. The use of this power awaits action by Congress on a general water power bill.

The main 48-ft. drop at St. Anthony Falls is largely used for grinding flour, the most important engineering activity of Minneapolis. The flour mills have a story of their own, and this will be told at the mills to visitors. The annual production of high-grade flour ranges from 16,000,000 to 20,000,000 barrels.

Half a mile downstream from St. Anthony Falls, a second development exists with a fall of 18 ft., used by the local traction company.

Power Auxiliaries Needed

As the flow of the Mississippi River sometimes dwindles to 1000 cu.ft. per second in mid-winter attenuation, great steam auxiliaries are everywhere supplied. The Riverside station of the Minneapolis General Electric Co. with its recently installed 25,000-kw. turbo-generator, is the most colossal auxiliary of the Twin Cities, supplying current to the mills and other manufactories, and to public utilities as well, in times of low river flow.

The water power plants and water power sites of the Northern States Power Co. on the Mississippi and St. Croix Rivers represent engineering activities, existing and of the near future, of great interest. The Main St. station develops a portion of the St. Anthony Falls power. The Coon Rapids dam, with 18-ft. head, completed in 1914, is on the Mississippi River about 11 miles above Minneapolis. The Taylor's Falls plant of this company, on the St. Croix River, about 41 miles by transmission line from Minneapolis, has a fall of 60 ft., and 20,000 installed horsepower, mostly used in the Twin Cities for manufacturing and public utilities. The undeveloped dam sites of this company on the St. Croix and Mississippi Rivers represent in their future development problems of exceeding interest. Some of these dams will be on rock foundations and some of them will mean 30 or 40-ft. heads on glacial-drift foundations; which will call for most skillful planning and execution, and will doubtless, when constructed, mean long strides of advance in the art of dam building on porous foundations.

No summary of the engineering activities pivotal on the Twin Cities can omit mention of the great head-water reservoirs of the Mississippi River. These reservoirs have utilized two large and several smaller natural lakes. Their combined capacity is over 100,000,000,000 cu.ft., with a watershed area of about 4000 square miles, and an additional water area of over 400 square miles.

Controlled by the Federal proprietor, who by law must regard navigation, however little it is, as the predominant interest to be served, the release of water is not always beneficial to the water powers, and sometimes is detrimental, as in midwinter when power needs are great and river flow meager. The water powers are really at the present time a greater public resource here than navigation itself. The benefit in vessel draft is about 1 ft. at St. Paul, tapering off to zero perhaps a hundred miles downstream. I imagine it will require an act of Congress to modify the release of reservoir storage so as to give the maximum benefit to the important water powers of the Mississippi. The attitude of the Federal proprietor is likely to change when the Federal water power at the high dam becomes a beneficiary.

The things discussed thus far represent engineering activities which are inherent in the physical and geographical characteristics of the Minnesota region. The existence of these things has caused great aggregations of people to cluster here. This population must be served by many engineering activities. Railways must bring to them many things to supplement the regional products, and must take away the things produced here. Minneapolis and St. Paul are two beads threaded on five transcontinental lines; and four axial north-and-south lines reach toward the Canadian store house and the cotton belt. Locally we are excellently served by a traction system which is suffering from 5-c. fares and franchise uncertainties.

Water-Supply

The water-supply here cannot fail to represent an engineering activity of transcendent interest — more particularly after July 1. The Mississippi River which has served so efficiently in the past in bringing forest production to Minneapolis brings also the sewage of the City of Anoka, 20 miles upstream. Minneapolis uses the Mississippi River, as it departs southward, to convey its sewage to St. Paul. These two facts made Mississippi River water a bad beverage for Minneapolis, and an impossible source of water-supply for St. Paul. Up to 1912 Minneapolis did pump its domestic supply unpurified from the river, notwithstanding the malign contributions from Anoka. Well-to-do people bought spring water crystalline clear in bottles. Venders sold water as they now sell milk—only seven years ago. The poor and the careless had winter cholera and typhoid fever. The first civic awakening dosed the water with chlorine, which helped while the present mechanical filtration plant was planned and constructed. Investigations for a better water-supply gave consideration to four possible sources. Lake Superior, 140 miles away, was alluring. Mille Lacs, a lake 207 square miles in area, 70 miles away, was enticing. The subterranean artesian supply, rising by gravity to perhaps 100 ft. below the street level here, had many advocates. The Mississippi—"a poor thing, but our own"—could not be overlooked.

The investigations resulted in the rejection of the Lake Superior source as too distant, the Mille Lacs supply as inadequate, the artesian as too hard and too uncertain, and the acceptance of the sometimes turbid, sometimes defiled, but always adequate, Mississippi River water, which by skillful engineering processes has been relieved of its baser ingredients and converted into a crystalline, wholesome supply. The typhoid rate in Minneapolis is singularly low. Schools and hospitals freely use the domestic supply for drinking purposes.

and all persons may meet confidently the era of alchoholically dry days.

St. Paul secures its water-supply from a group of lakes, reinforced by the artesian flow.

In concluding this meandering talk on the things conceived as of vital engineering interest to the Twin Cities and their zones of influence, I wish to speak for a few minutes of the most important inland navigational resource of the world, which now brings steel vessels built on the Clyde in Scotland to our Minnesota harbor at Duluth. As the Mississippi River gives Minnesota a water route to the Gulf of Mexico, the Panama Canal, the Pacific Ocean and the Orient, so the Great Lakes lead to the Gulf of St. Lawrence, the blue Atlantic, England, France, the Mediterranean, the Suez Canal and the Indies. Minneapolis is at the utmost inland reach of the Mississippi, and Duluth at the utmost inland reach of the Great Lakes.

Nowhere exist such alluring, splendidly big engineering things, solved and unsolved, as in this chain of magnificent lakes and stately rivers. It has been my privilege to have had a part in the things solved, and it is still my privilege to work on the things unsolved, and I regard myself as peculiarly blessed in working within such far-reaching horizons.

The hematite ore of Minnesota is vitalized and made marketable—80 per cent of the whole country's supply —by this waterway, which carries the ore to the coal, and brings coal to some of the ore smelted at Duluth. It is probable that the bulk of this ore would lie unmined and unused were it dependent on rail transportation. It costs roundly $1 a ton to get the ore by rail 100 miles from the Missabe Range to the lake shore at Duluth, and it costs $1 to cary this ton of ore 1000 miles to Buffalo.

The tonnage passing the big ship locks in St. Mary's River, at the foot of Lake Superior, exceeds the combined tonnage of the Panama and Suez Canals.

Exit to the sea is still limited by the shallow drafts of the Erie, Welland and St. Lawrence Canals. But the Welland Canal is building now for 25-ft. draft in the canal prism and 30-ft. draft in the locks; and the St. Lawrence waterway will follow this lead. That is one of the big engineering things. The New York State Barge Canal shrinks to a trifling thing, with these great projects evolving.

The Chicago Drainage Canal, diverting a considerable stream of Lake Michigan water, has created the need of the regulation of Lakes Michigan, Huron, Erie and Ontario, by controlling work in the outflow rivers—Niagara and St. Lawrence in particular. St. Mary's River, the outlet of Lake Superior, is already under artificial control, in the interests of navigation and water power; and projects are maturing for the manipulation of the outflow in the Niagara and St. Lawrence Rivers. Each year, to a greater extent, it is realized that after all the lakes are storage reservoirs of almost limitless capacity and incalculable value. Nature has one sole motive in her operation of the outflow rivers, which is to rush the waters to the sea. The water returns through the heavens, and the endless cycle of rainfall and outflow goes on. But this water, when engineers intervene, must be made to serve better the artificial uses of navigation and power.

So it will come to the point where we must *budget* the water eventually—why not now?

Budgeting the water means spending it systematically and scientifically, in well thought out apportionments, which will make the Niagara and the St. Lawrence better navigable ways and better water power streams.

Water power is really the thing which inflames the imagination. Aladdin with his lamp never conjured genii to serve him so omnipotent as engineers have made emerge from seaward-bound waters. And the Niagara and the St. Lawrence descending to the ocean held in their depths potentialities to assume tremendous burdens of labor which still pitilessly strain human muscles.

In these things of which I have spoken I conceive to be in the largest sense the significant engineering activities of the Twin Cities.

Results of Long-Time Tests of Creosote-Treated Fence Posts

By C. H. Teesdale
Engineer in Forest Products, Forest Products Laboratory, Madison, Wis.

Over 2000 fence-posts were treated and set during 1908 and 1909 by the United States Forest Service, in coöperation with the University of Minnesota. Quite a number of these posts were treated with water-gas-tar creosote and others with coal-tar creosote, the hot and cold bath open-tank method being used and the entire post treated. An inspection in the summer of 1918, 9½ years after the posts were set, gives some interesting information, as it affords a direct comparison between coal-tar creosote and water-gas-tar creosote as wood preservatives. The table gives results from three inspections of these posts in 1913, 1916 and 1918.

BASSWOOD AND RED OAK POSTS TREATED BY COAL-TAR AND WATER-GAS-TAR CREOSOTE

Treatment	Species	Years of Service	Inspected	Number Tested	Good, %	Partly Decayed, %	Badly Decayed, %	Removed Account Decay, %
Coal-tar	Basswood	4½	1913	458	93.0	6.3	0.5	0.2
Creosote	Basswood	7½	1916	484	87.0	9.5	3.1	0.4
Creosote	Basswood	9½	1918	337	73.5	17.4	4.4	4.7
Water	Basswood	4½	1913	35	100.0	....	...	...
Gas-tar	Basswood	7½	1916	36	86.0	8.3	5.6	...
Creosote	Basswood	9½	1918	27	78.0	14.7	7.3	...
Coal-tar	Red Oak	4½	1913	226	100.0	....	...	...
Coal-tar	Red Oak	7½	1916	325	99.2	0.8	...	...
Creosote	Red Oak	9½	1918	330	94.5	1.8	1.2	2.5
Water	Red Oak	4½	1913	42	100.0	....	...	...
Gas-tar	Red Oak	7½	1916	98	97.0	1.0	2.0	...
Creosote	Red Oak	9½	1918	93	92.5	5.4	...	2.1

It is seen that at the last inspection 73.5% of the basswood treated with coal-tar creosote and 78% of that treated with water-gas-tar creosote were still sound. In the case of red oak 94½% treated with coal-tar creosote and 92½% treated with water-gas-tar creosote were still sound. It was found that the basswood posts did not take the treatment well, and for this reason this species is not recommended for open-tank treatment.

River Water Treated for Compensation Supply

To fulfil its obligations to supply compensation water to satisfy riparian or power rights, the City of Sheffield, England, will treat 9,000,000 Imp. gal. of Don River water per day to fit it for industrial use and pump it 11 miles back into the Loxley and Rivelen Rivers, tributaries of the Don. The water will be taken from the Don below Sheffield. Parliamentary authorization was required, and the committee hearing occupied 13 days. The London *Surveyor* states that this is new principle as to compensation water.

Enlargement of the Yakima-Tieton Main Canal

Half Circular Section of Reinforced Concrete Increased in Height—Bonus System Successful in Overcoming Great Scarcity of Labor at Favorable Cost

By G. C. Finley
Engineer United States Reclamation Service, Yakima, Wash.

UPON the extension of the boundaries of the Tieton Project of the Reclamation Service in the State of Washington from 24,000 acres to 32,000 acres, it became necessary to increase the capacity of the Tieton Canal. The reinforced-concrete section of this canal was circular, open at the top, slightly exceeding a semi-circle in cross-section. To enlarge the canal, a new top segment on each side was cast in place after the old concrete bracing ties were removed and a notch was cut for bonding the old to the new concrete. An acute labor situation was successfully met by introducing a bonus system, which also resulted in more than doubling the amount done per day, making possible the completion of the work, as desired, last fall.

The Tieton Canal was constructed by the United States Reclamation Service during the period from 1907 to 1909, and has been used to carry water for irrigation for the past eight years. The Tieton project, to which this canal supplies water, covers 32,000 acres, of which 26,000 acres are in a high state of cultivation. This past season there was produced $2,500,000 worth of foodstuffs, and the water duty was 2.36 acre-feet delivered on the farms.

The canal was originally constructed of reinforced concrete in sections on the flats along the river, the sections being transported to the canal site, then placed and grouted together. The sections were circular in form, 8 ft. 3⅝ in. in diameter, the top edge being 22 in. above the horizontal diameter and tied together by a 4 x 6-in. reinforced-concrete bar. They were built 2 ft. long and 4 in. thick, reinforced with ¼-in. steel longitudinally and ⅜-in. circumferentially.

The canal varies in elevation above the river from 0 at the point of diversion to 500 ft. at the lower end, and is constructed along a very rough and precipitous cañon wall. Fig. 1 shows a section of the original canal as completed in 1909.

Enlargement Necessary—The canal was designed and constructed for a project of 24,000 acres, but the boundaries of the project were subsequently extended to embrace 32,000 acres. This increase in area and a growth of algæ which reduced its capacity somewhat made it necessary to enlarge the canal section to carry the required quantity of water. The enlargement of the entire canal was begun in the fall of 1916, was continued in the fall of 1917 and then finally completed in the fall of 1918. Due to weather conditions in the Tieton Cañon and the necessity for continuing the operation of the canal, the working season was only from the first of October to about the middle of November, or about seven weeks each year.

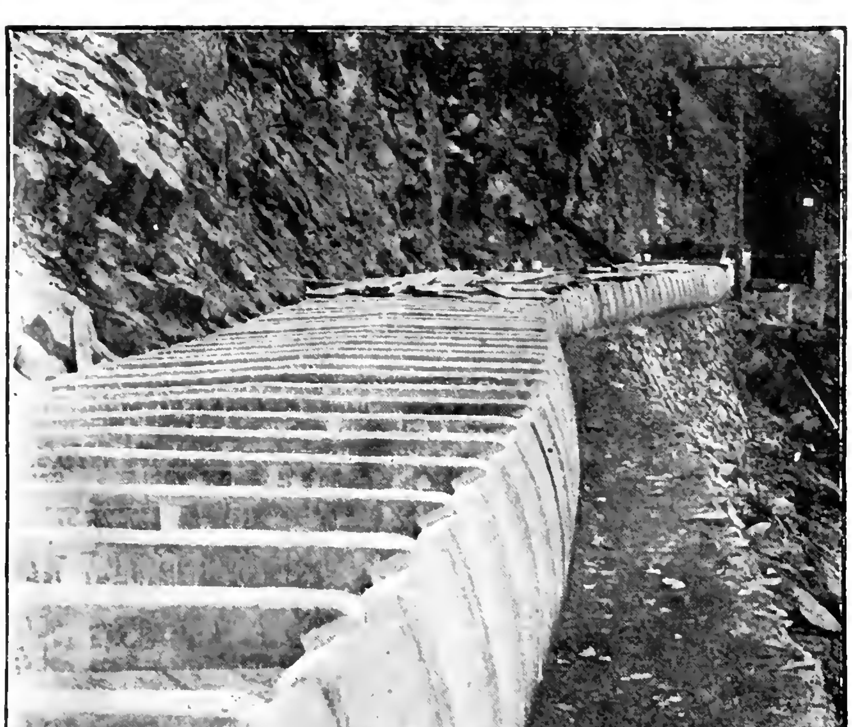


FIG. 1. ORIGINAL CANAL SECTION AS COMPLETED IN 1909

FIG. 2. TRANSPORTING CEMENT BY TRAMWAY

The necessary materials consisted of cement, sand and gravel, structural and reinforcing steel, and lumber for forms. The cement, steel and lumber were hauled by motor truck from Naches, an average distance of 15 miles. The aggregate was all hauled by teams from various points along the river, either direct to the canal or to the foot of tramways. The sand was screened through a ¼-in. mesh, and the gravel passed through a 1¼-in. mesh. Fig. 2 shows how the cement was transported at one point of the canal by inclined track and tramway.

One of the big problems was the distribution of materials along the canal. There were various parts of the canal up to 1½ miles in length where materials were delivered at only one point. This distribution was made by using mules hitched to small cars, as in Fig. 3. This work was first attempted by using men and cars, but the mules after the first few days were found to haul more load and make better time. The small stream of water shown running in the canal was used for the hoist boiler and for mixing concrete.

The preparation for joining the new work to the top of the original canal meant the removing of the concrete crossbars and the chiseling of a groove along the top of each side of the canal. This chiseling was first done by hand, but later by using two small pistol-grip

FIG. 3. MULES AND SMALL CARS USED FOR DISTRIBUTION OF MATERIAL ALONG CANAL

drilling machines run by an air compressor, operated by hand. Fig. 4 shows the canal as prepared for the enlargement. The hammers used for chiseling along the canal were found to work very successfully, in time and cost.

The old concrete crossbars were broken up and used for aggregate, and the reinforcing steel was salvaged. The new crossbars were made from 3-in. standard channels spaced 5 ft. apart and extended 6 in. into the old concrete. No provision for a contraction point was made in the new work, as 1% of temperature steel was provided and the work was all done during cool weather. To date there have not been any serious temperature cracks in the entire canal. The addition as constructed gave the canal a certain longitudinal strength as a beam, which may be of value in case of undermining. The maintenance work on the repair of the joints each season, due to temperature, has been materially reduced. Fig. 4 gives the general dimensions and details of the enlarged section.

Form Construction—Forms made of 1-in. surfaced cedar were used for the work and placed to grade by using a Y-level. The inside surfaces were all pointed with linseed oil twice during each season. Fig. 5 shows how the forms were placed, also the structural and reinforced steel and materials as they were placed.

Fig. 6 shows the manner in which the concrete was mixed and placed. The work was carried on by a number of crews of about 18 men, each in charge of a foreman. Each crew used about 600 ft. of forms, of which about 250 ft. were removed each day and moved ahead and refilled. The mixing and placing were all done by hand, the mix being 1 : 2 : 4 with sand and gravel aggregate. The mixing was done on a board supported above the canal by wooden horses which were moved forward along the canal. The concrete when mixed was shoveled direct into the forms. The forms were removed in 48 hours, and, because of careful mixing and tamping very little finishing was found necessary. The original canal was raised by placing the forms tangent to the curve a sufficient distance to make 1 ft. in elevation. The progress of the work from the beginning in 1916 until the close in 1918 varied per crew from 140 to 400 lin.ft. of canal per day.

Fig. 7 gives a view of the present completed canal, showing the steel crossbars, new work and the point of contact between the original canal and the enlargement. The capacity has been increased from 300 cu.ft. per second to about 350, which will be sufficient for the full development of the project.

Weather conditions during the working season on the canal were generally favorable, and especially during 1918 the weather was perfect, with no time lost on account of rain and no concrete damaged on account of cold weather. There was an average of 12 hours daylight during the working season.

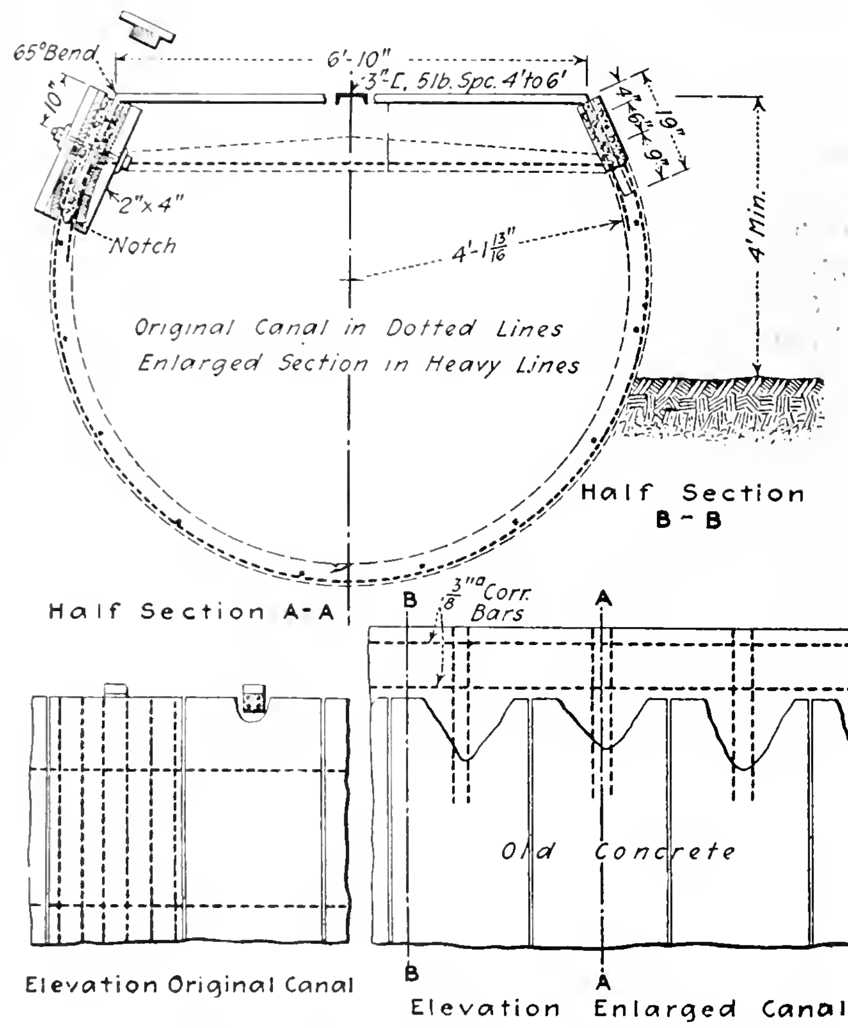

FIG. 4. DETAILS OF ORIGINAL AND ENLARGED SYSTEMS

Labor Situation—The local supply of labor during 1918 decreased rapidly from early spring on account of shipbuilding, logging and other war industries offering high wages on the coast, and, beginning with the need for farm labor in the valley about June 1, the labor situation in general began to look very serious for construc-

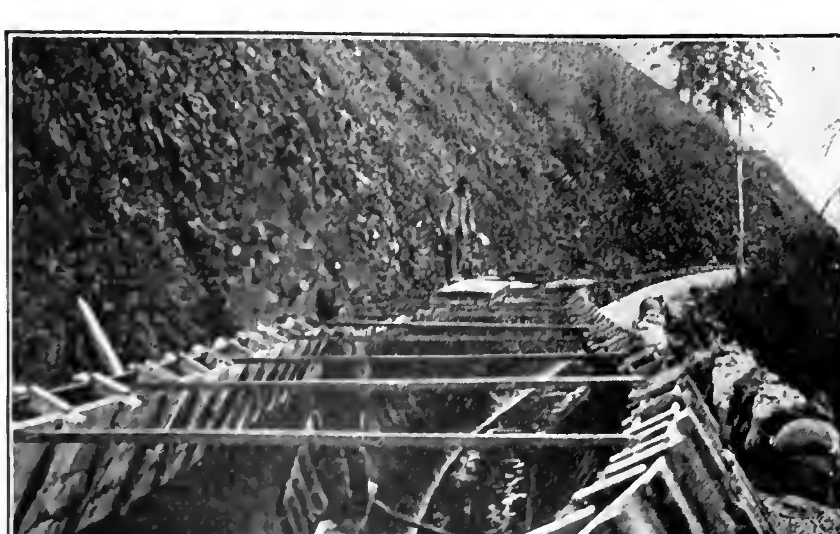

FIG. 5. BRACING AND FORMS IN PLACE

tion work of any kind. Wages were increased about 50%, which made the cost almost prohibitive.

The only time during which the enlargement work on the Tieton Canal could be done was the month of October and the first half of November. This was during the time when the farmers were harvesting their third cutting of alfalfa and practically the entire apple and potato crops, all three of which are produced in large quantities in the Yakima Valley. Prices for farm crops in general were most favorable, so that farmers were paying almost any price in order to obtain sufficient

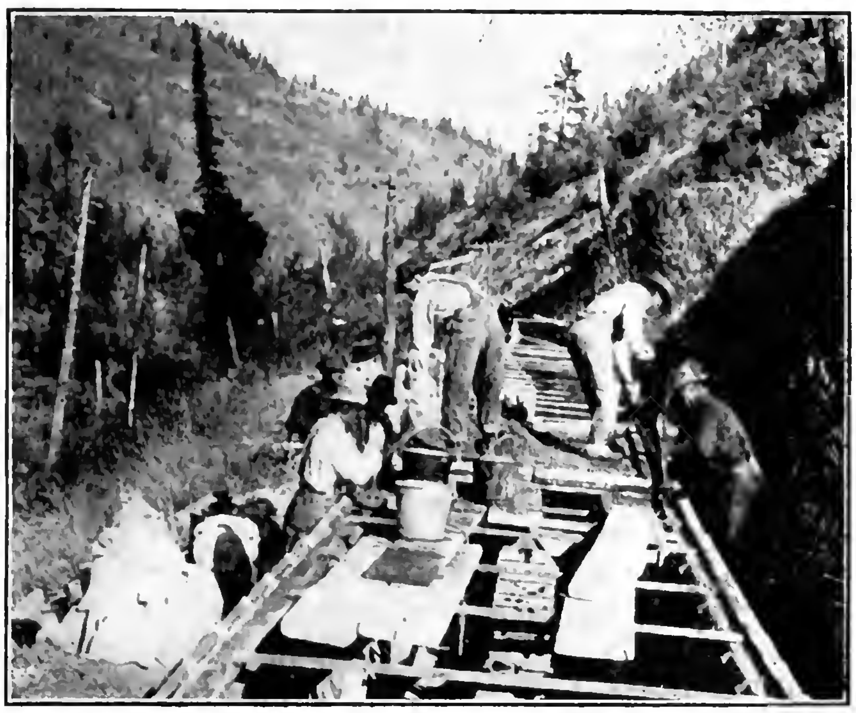

FIG. 6. HOW CONCRETE WAS MIXED AND PLACED

labor for harvesting these crops. Concrete work, especially where the mixing is done by hand, is not attractive to the average laborer because everyone knows it is hard work. Furthermore, a similar job was in progress where wages and living conditions were favorable, only about one-third the distance from Yakima, and this camp was not able to obtain sufficient men.

The estimate of the number of men necessary to complete the remaining work on the canal in the time required was about 160. This meant five crews of about 18 men each, mixing and placing, and the necessary labor to supply material. There were about 40 men in camp who were doing such preliminary work as building roads, erecting a tramway, building forms and screening sand and gravel. On Oct. 1 we were in need of about 120 more men. Labor for construction work in the Yakima Valley is obtained through Spokane and Seattle; many make Yakima their local headquarters.

Bonus System—In order to assist in the solving of the problem of getting sufficient labor while weather conditions were favorable, a bonus system of wages was adopted. The work had been started in 1916 and continued in 1917, and the plans were to complete the job in 1918. There were 126 stations completed in 1916; 97 stations in 1917, and 254 stations remaining. There had always been a labor shortage on this work, but especially during 1917. In 1916 the average progress was 150 ft. per day; in 1917 this average was brought up to 160 ft. per day.

As is the practice in establishing a bonus rate, the cost is divided equally between the employer and employee for any amount of work done over and above what is considered an average day's work, amounting to about 3c. per man per foot. Laborers must have a certain amount of bonus in order to become interested, and it was decided that 140 ft. per day should be counted as a good day's work. Therefore, each man in the crew received 1½c. per foot each day for any amount completed over 140 ft. The granting of this bonus was contingent on a man working 10 days, and the amount of bonus was determined on each 10-day period.

COST OF ENLARGEMENT WORK—TIETON MAIN CANAL

	1916	1917	1918	Total
General Costs				
Stations enlarged during year..	126	97	254	477
Number of yards of concrete placed	433	333	874	1,640
Cement delivered	$2,926.36	$2,373.34	$4,767.87	$8,567.57
Sand and gravel delivered	4,292.25	3,491.71	7,679.55	15,463.51
Forms, labor and materials	2,583.61	1,655.82	6,632.71	10,872.14
Mixing and placing concrete	1,921.22	1,881.47	11,535.61	15,338.30
Finishing and protection	666.47	759.39	2,715.97	4,141.83
Equipment charge	831.46	375.77	1,854.73	3,061.96
Unit Costs				
Cost of cement delivered in barrels	$3.85	$4.10	$4.15	....
Lumber delivered—per thousand	11.00	......	17.00	....
Wages paid for labor—base rate	2.40	3.00	4.50	....
Cost of reinforcing steel—per lb. in place	0.045	0.054	0.062	....
Cost per cubic yard of concrete	30.54	31.64	40.26	35.00
Final Costs				
Preparation, chiseling, etc.	$1,793.87	$1,995.37	$7,458.03	$12,747.27
Reinforcing steel in place	1,175.52	1,101.29	3,738.40	6,015.21
Steel crossbars	5,656.11	6,137.41	12,276.76	24,070.28
General expense	1,595.40	2,146.36	5,268.44	9,010.20
Total cost of work	23,442.27	21,917.93	63,928.07	109,288.27
Cost per lineal foot of canal	1.86	2.26	2.52	2.30

The cement haul was by teams in 1916 and 1917, an average distance of 18 and 16 miles. In 1918 motor trucks were used and the average distance was only 10 miles.

No lumber was bought in 1917, old forms being used.

Structural steel purchased in 1918 was 1¼-in. reinforcing steel and not 3-in. channels, as previously used, because it was impossible to purchase the standard channels.

During the first two bonus periods the average amount of work was about 200 ft. per day. During the third bonus period this average was brought up to 220 ft. per day. The interest in this system of paying for work seemed to grow from the beginning of the work, and during the last period, which was from Nov. 10 to the date of completion, Nov. 18, 1918, the average

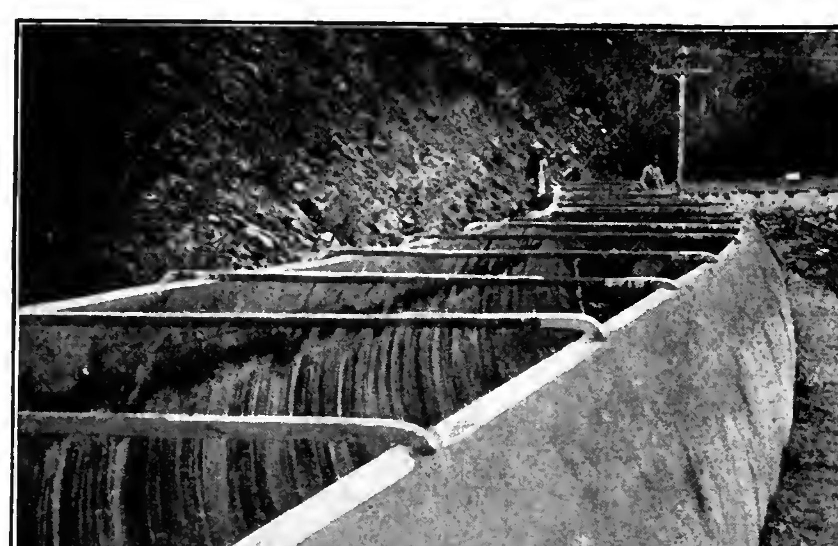

FIG. 7. COMPLETED CANAL SECTION AFTER ENLARGEMENT

was 300 ft. per day, with a maximum of 404 feet.

Without a doubt, the result of this system of wages was very material in obtaining sufficient men to complete the work. This scarcity of labor was such that only three crews were working until Oct. 25, and four crews from this date until the completion of the work. There was an increase daily of the number of men in camp from 40 at the beginning of October to a maximum of 160, the increase being gradual. There was very little trouble in holding the men on the work, as wages in general were good and so was the mess.

Figuring the cost of the work done in 1918 carried out under the prevailing wages without bonus, using the work done in 1916 as a basis, it amounts to $3 per lineal foot, which was the estimate prepared for the work. The main result of the bonus system was that it proved to be a sound basis for productive efficiency. The entire canal was completed, and the figures show that the advance in costs in 1918 is considerably below the general advance in labor and materials.

The work was done under the supervision of R. K. Tiffany, project manager of the Yakima Project, with the writer as engineer in direct charge of the work.

Save $10,000 by Breaking Old Stone Across the Bed

Salvaged stone from an old boiler house at the river pumping station of the Louisville Water Co. was broken across the bed and its use on the new boiler house under erection has saved $10,000.

The old structure was 75 ft. square and 25 ft. high, and built of solid stone from Bedford, Ind. The new one is 75 x 150 ft. in plan and varies in height from 25 to 85 ft. It is similar in construction to the pumping station described in *Engineering News-Record* of May 9, 1918, p. 905, being faced with 6 in. of stone and backed up with reinforced concrete. The stone in the old building varied in thickness from 6 to 8 in. and in length from 3 to 4 ft., all being headers 2 ft. wide, faced on both inside and outside. Thus, hauling the stone six miles each way to the mill for sawing and refacing would have entailed considerable expense, making the cost practically the same as that of new stone. All of the stones were laid on their beds, and every stoneman who passed on the work said it could not be split across the bed except by sawing and drilling. The best price obtainable for sawing and refacing with a rock face and loading on cars at the factory was 57c. per cubic foot. The 25,000 cu.ft. has been done, according to J. A. Wilson, chief engineer and superintendent for 14c. per cubic foot with little breakage.

The splitting of each stone into three pieces was done by laying the piece to be broken on a bench made of 12 x 12-in. timbers, placing under the stone a $\frac{3}{4}$-in. iron rod and striking 6 to 10 blows with a 12-lb. hammer.

Calcium-Chloride Solution and Setting of Concrete

Results of Numerous Tests Show That Strength of Concrete Is Not Lowered—Hastens Setting Materially

CALCIUM-CHLORIDE solution materially hastens the setting of portland-cement concrete, and new tests have shown that up to the end of one year the strength of the product is not injured, according to the annual report of H. Eltinge Breed, until recently first deputy commissioner of highways, New York State Highway Department, and now consulting highway engineer, New York City.

In leading up to the portion of his report reproduced below, Mr. Breed stated that, although the department had had unusual success in doing its own construction work upon its unfinished contracts—in fact, so successful that the question is raised as to whether it might not be advantageous for highway departments to be authorized and prepared in emergencies to do their own construction as well as engineering work—still, he felt that perhaps the best contribution made this year by his department to the good-roads movement in the state and elsewhere was through the medium of its research work.

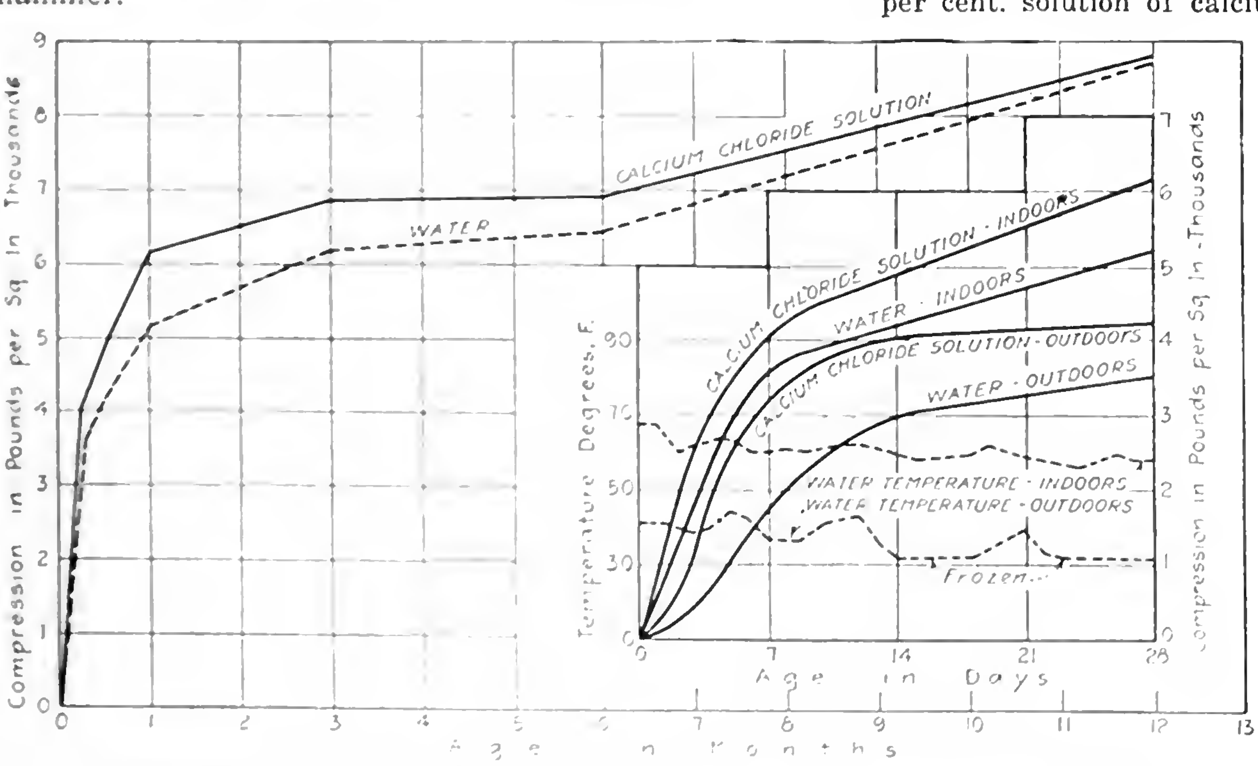
Important phases of this research work are the impact studies, described in *Engineering News-Record*, June 5, 1919, p. 1103, and the experiments with calcium-chloride solution. The following is an extract from Mr. Breed's report referring to the latter:

A series of tests were completed to determine the advantages in use of calcium-chloride solution to hasten the setting of cement concrete. It has been stated that by use of this solution concrete gun foundations could be put in use three days after construction. The tests made by this department were for the purpose of determining whether the rapid setting would decrease the ultimate strength which the concrete would attain. It is well known that abnormally quick setting cements do not usually make concrete which is as strong ultimately as the slower setting cements.

Laboratory test samples were prepared and tested at ages varying from one day to one year. The results are shown graphically herewith. They indicate the use of a 4 per cent. solution of calcium chloride as mixing water for cement concrete increases the strength attained at all ages up to one year.

Beyond that it is still problematical, but what evidence we have indicates certainly no deterioration, and a probable continued, but slower, gain. The maximum increase appears to be about 20 per cent. at the age of one month.

The importance of this determination will be appreciated when it is considered that by the use of this solution it will be possible not only for the contractor but also for the public to make use of cement-concrete pavements a few days after they have been laid, without risk of damage. It will mean the completion of much work in the autumn which has hitherto had to wait over unfinished until spring.



STRENGTH OF CONCRETE WITH AND WITHOUT CALCIUM CHLORIDE.

Sinking and Concreting Mine Shaft 936 Feet Deep

Lining and Walls of Four-Compartment Shaft No. 5 of Miami Copper Company Concreted Simultaneously With Excavation Operations—Blasting Impossible Below 200-Foot Depth

By Richard L. Russell
Superintendent, The Foundation Company, Miami, Ariz.

Several novel details in underground construction were developed and applied in the sinking and concreting of shaft No. 5 of the Miami Copper Co. at Miami, Ariz. This shaft has four compartments and is 936 ft. deep, and the concrete lining was carried on at the same time as, and without interference with, the sinking, 700 ft. of the shaft lining having been placed and two large stations having been excavated and concreted by the time the shaft had reached its final depth. The section, shown in Fig. 1, is 13 ft. x 16 ft. 4 in. clear and required an excavated section 15 x 19 feet.

The entire shaft lies in what is locally known as Gila

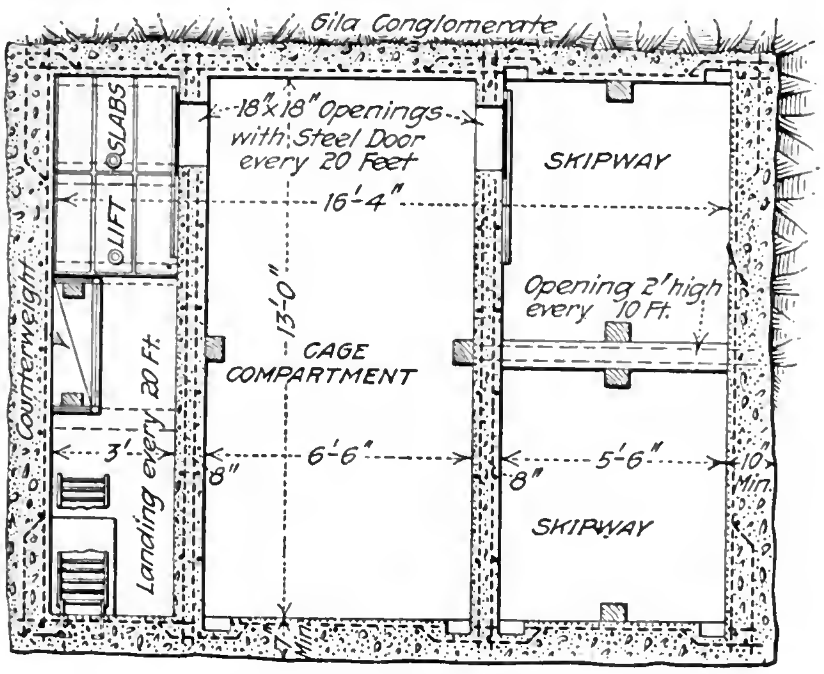


FIG. 1. CROSS-SECTION OF SHAFT, SHOWING CONCRETE LINING

conglomerate, a formation which is typical hardpan rather than a true conglomerate. Although the material is very hard, no blasting was done after water was encountered at a depth of about 200 ft., it being found practically impossible to remove the powder fumes from the fissures in the water-laden hardpan. Light jackhamers with "bull points" from 2 to 3 ft. long were used to break the ground. This method, besides permitting the walls to be trimmed neatly, with far less overbreak than would result from blasting, permitted a progress of 100 ft. per month.

The shaft was located on the side and near the top of a small, steep hill, the top of which was graded down by the contractor to the elevation of the collar of the shaft. The plant layout is shown in Fig. 2. The shaft being near the present operating plant of the Miami Copper Co., the air, water and electricity were delivered by that company at the collar of the shaft.

The contractor began erecting the headframe and other working structures Dec. 11, 1917, and hand excavated for the top 25 ft. of shaft without blasting, in order to avoid disturbing the ground adjacent to the collar. As the hoist could not be delivered until the end of January, 1918, the contractor obtained, late in December, permission to drift in from a tunnel of the Miami Copper Co. which passed within 20 ft. of the southerly corner of the shaft at a depth of 118 ft. This permitted the tramming of muck by hand a distance of about 300 ft. through the tunnel to a dump in the gulch at the tunnel entrance.

After the line of the shaft was reached, a raise was driven for the purpose of meeting the excavation from the surface. This raise was 2½ x 6 ft., of which 2½ x 2 ft. was a manway with ladders and the remaining space was occupied by a cribbed chute. At the tunnel level the drift was widened and the full shaft section excavated to make a working chamber large enough to accommodate a switch, which permitted the sidetracking of an empty car while another car was being loaded.

The full section of the shaft was then broken down through this chute by the use of 40% dynamite.

The drift was started Dec. 26, 1917, and completed Jan. 1, 1918; the raise was started Jan. 2, 1918, and completed at 6 a.m. Jan. 8, 1919—a rate of 5 ft. per eight-hour shift. The full section of shaft was excavated to the level of the tunnel Feb. 20, 1919, and 60 ft. of shaft had been concreted in the same period, as follows:

As soon as the excavation had reached a depth of 35 ft. the forms for the 25-ft. collar were started on 12 x

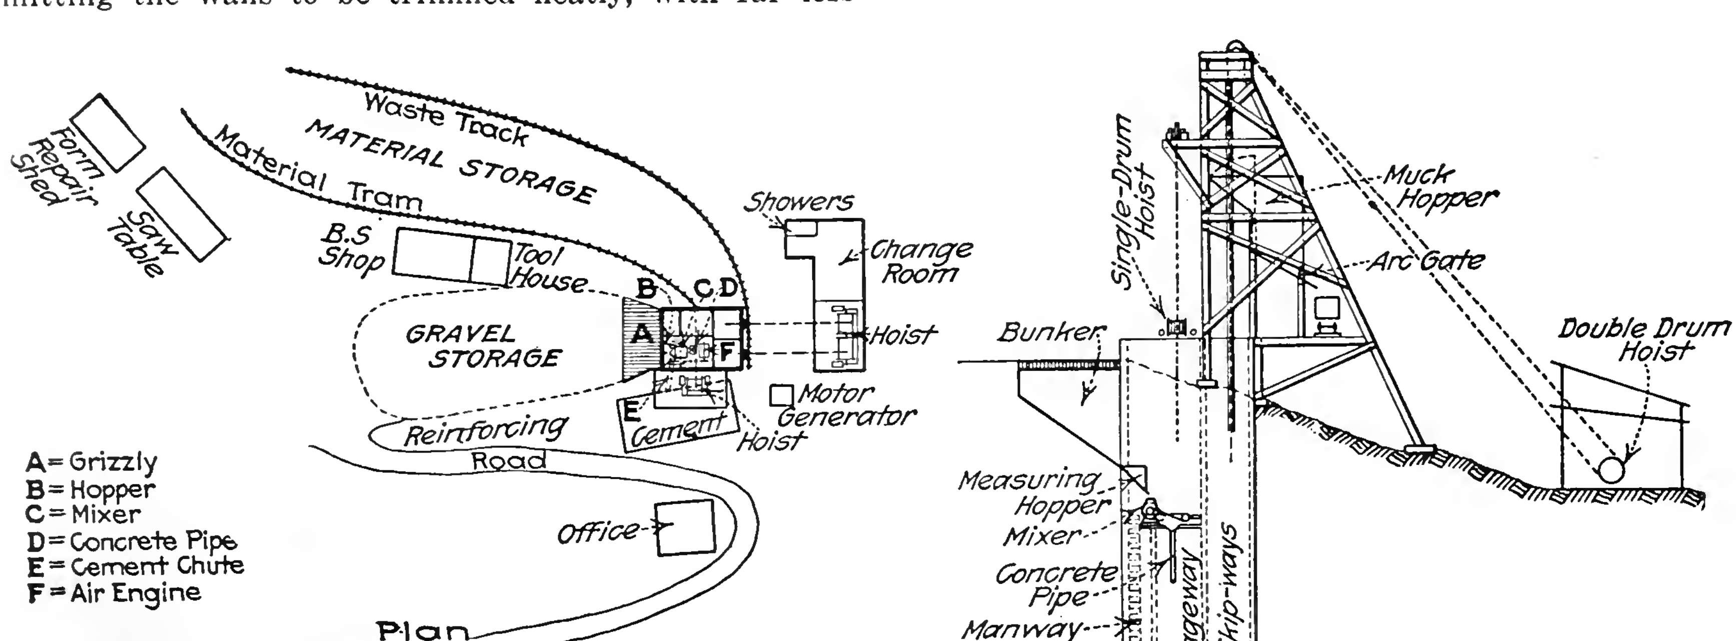

FIG. 20. PLAN OF CONSTRUCTION-PLANT LAYOUT FOR SINKING AND CONCRETING MINE SHAFT

12-in. bearing timbers placed in 18-in. hitches cut in the hardpan walls. No back forms were used, and the whole 25 ft. was poured continuously. As no water was encountered, no timbering was necessary.

While the collar was being concreted, the excavation had progressed to a depth of 55 ft. Hitches were again cut in the walls, and the three 12 x 12-in. bearing timbers were lowered into them. On these bearing timbers was placed a timber frame, the exact size of the concreted section, which served both as a bottom form and a sill on which the form panels could be set. The vertical reinforcing rods were then hooked to the verticals which had been left projecting from the bottom of the previous concrete, and the horizontal reinforcing was wired to the verticals. A 5-ft. section of forms was then placed and concrete was poured, this process continuing until the concrete was carried up to the bottom of the collar section. It was found that the ground would safely permit the opening up of a depth of fully 25 ft. of shaft without lateral support, and the concrete was carried down in 20-ft. sections by the above process for the first 200 ft. of the shaft.

As soon as the raise from the tunnel level was finished and the breaking-down process was well under way, a small air hoist was installed at the tunnel level, and the two skip compartments were sunk and timbered as a pilot shaft, this muck being hoisted to the tunnel level and also trammed through the tunnel. Thus excavation was being carried on simultaneously at two levels

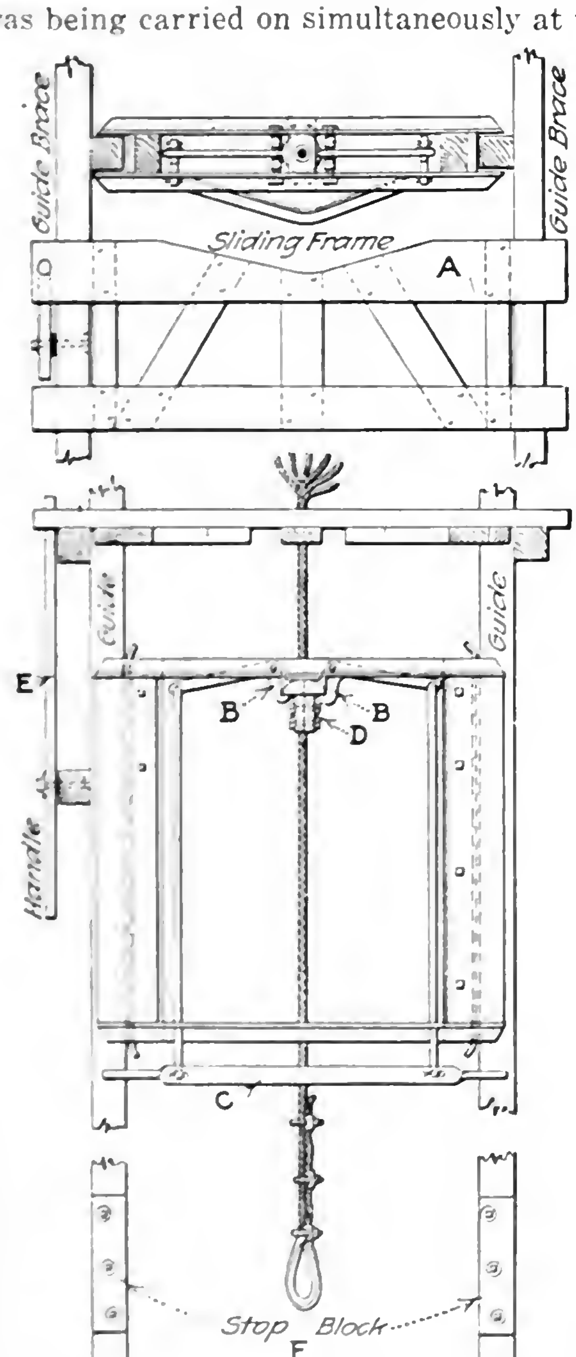

FIG. 3—CROSS-HEAD AND SAFETY DEVICES

without interference, while waiting for the double hoist to be delivered.

By the time the whole shaft had been excavated down to the tunnel level a two-compartment pilot shaft 100 ft. deep was ready, one compartment serving as a chute through which to draw off the muck from breaking down the full section of the shaft and the other a hoisting compartment to the tunnel level through which the muck was still trammed.

Water was encountered at this depth (218 ft. below the surface) and while the full shaft section was being excavated to this depth the double-drum hoist was delivered and installed and a special crosshead was devised to comply with the requirements of the Arizona mining laws and at the same time permit the bucket to be dumped into the receiving bin in the headframe without excessively increasing the height of the latter.

As it was neither possible nor desirable to keep the bucket guides extended nearer the bottom than 15 to 30 ft. while sinking was in progress, this crosshead had to be such that it could be stopped at any desired point in the shaft as well as at the headframe and allow the bucket or skip to continue on, for filling or changing at the bottom or dumping when reaching the headframe. This was accomplished by the arrangement shown in Fig. 3.

A lug D was securely clamped to the cable about 6 ft. above the shackle loop. This lug engaged the dogs B and thus attached the crosshead securely to the cable. When the crosshead reached the top of the headframe, the top lander pulled the lever E and slid the frame A over against the guides and gave the lowering signal. The bumper C then hit the frame A, the dogs B released the lug D and the crosshead was left resting on the frame A while the bucket was dumped, after which the latter was raised high enough to take the crosshead off the frame A. The frame was then slid back and the bucket with the crosshead attached was ready for lowering. At the bottom of the shaft, or at any other point where free use of the bucket was desired, stop blocks E were bolted to the guides and performed the same function as the frame A at the headframe. This crosshead gave perfect satisfaction.

From the 218-ft. depth to the bottom the full section of shaft was excavated by the use of bull points; three men using jackhamers working them into the material loosened all that four muckers could load into the buckets.

It was found that the water caused the hardpan to slough very treacherously soon after a wall was exposed. Full timbering was therefore carried on with the excavation from the 250-ft. depth; 8 x 8-in. plates, posts and dividers and 2-in. lagging were used. Corner joints were framed as shown in Fig. 4 in order to secure an increased bearing surface. As the shaft was concreted, all timber and lagging were removed and re-used, some timbers being used as many as four times. This not only resulted in a large material saving but also saved a high framing expense, as carpenters were paid $7.25 per shift at that time.

The section concreted in one operation was increased to 100 ft.; that is, the 12 x 12-in. bearing timbers were lowered 100 ft. and set in hitches and the 100-ft. section was concreted upward in 5-ft. courses.

The water was bailed into buckets and hoisted, five buckets per hour, or 600 gal. which, together with the

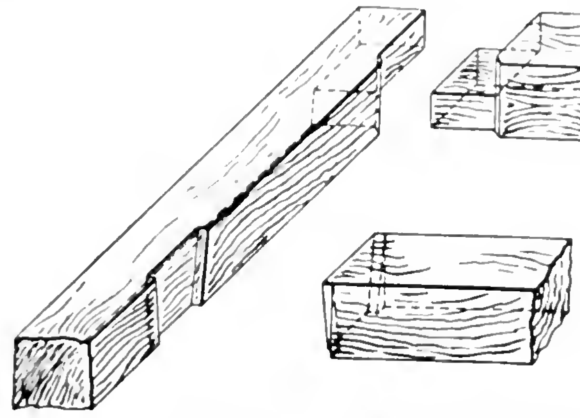

FIG. 4. DETAIL OF TIMBER FRAMING

water shoveled and hoisted with the muck, was sufficient to keep the bottom free. A timber bulkhead 6 in. thick was kept not over 50 ft. above the men working in the bottom over all of the shaft except the two skip compartments. While the reinforcing and forms were being set in one of the skip compartments all the hoisting from the bottom was done in the other compartments, and after the forms were set one of the skip compartments was bulkheaded at the level of the top of the forms, as were the cage and manway compartments, one skipway only being left open for hoisting.

Upon the completion by the contractor of the contract for lining with concrete the old shaft No. 3 of the Miami Copper Co., a mile distant from the new shaft No. 5, about Apr. 1, 1918, the single-drum hoist from shaft No. 3 was installed at shaft No. 5, as shown in Fig. 2, working from extension timbers from the same headframe and operating in the cage compartment.

This hoist handled all reinforcing, forms, concrete pipes and timbers to the form and concrete gangs, and as there was always a bulkhead in this compartment over the men in the bottom, the danger of working at two different levels was greatly lessened. This hoist was also used in pulling and resetting the rather heavy wooden forms in all compartments. It proved nearly as fast as a derrick and obviated the use of the slow and expensive block-and-tackle method.

Separate bunkers for sand and gravel were excavated immediately adjacent to the collar of the shaft at the manway end, and the sand and rock from the crushing plant, which was installed in the creek bed, was dumped through grizzlies into these hoppers. Through openings left in the shaft collar, with arc gates, the sand and stone passed into measuring hoppers inside the manway and cage compartments. These hoppers were of the proper dimension for a one-bag batch, and from these hoppers the material was chuted to a batch mixer located in the shaft cageway compartment 20 ft. below the surface. The cement was slid in bags down a chute from the door of the cement shed through an opening in the south side of the cageway compartment directly to the mixing plant.

The mixer, of 8-cu.ft. capacity, was belt-driven from a small air hoist set at the same level. This plant occupied the southerly half of the cage compartment and manway compartment, the wall between the two being omitted temporarily for its accommodation, the whole plant occupying an area only 7 ft. x 9½ ft., as clearance for buckets and material handled by the small hoist in the cage compartment had to be maintained at all times.

The 1 : 2 : 4 mixture of concrete was dumped from the mixer through a 6-in. iron pipe with screwed couplings and with the fall broken at junction boxes every 300 ft. and at the swiveled chute which carried the concrete to the forms around the shaft. This pipe was supported by timber clamps resting on 6 x 8-in. timbers carried in recesses left in the concrete when poured, and on the shaft timbers where the concrete had not yet been placed.

In the manway compartment the permanent iron ladders were placed in position as the concrete lining was placed. In advance of that, the permanent ladders were placed on temporary wooden landings. Concrete-lined stations were located at 235, 490, 576, 643, 729, 770, 835 and 920 ft. below the surface. The 490- and 576-, also the 770- and 835-ft. stations were the top and bottom of future ore pockets. The ore pocket between the 643- and 729-ft. stations is now being constructed.

To facilitate the construction of these pockets, 4 x 4-ft. cribbed chutes were excavated before the shaft was concreted just outside of the concrete walls of the northwestern skipway, with a gate and a chute leading into the skipway at the bottom of each pocketway. When the ore pockets are constructed the muck will be shoveled into these chutes and drawn off at the bottom and the cribbing removed as the excavation proceeds, thus effecting a considerable economy in the cost of excavation.

For the hoisting in the cageway compartment, cable guides were installed, carried on reels on the headframe and unreeled as the shaft was deepened, and even at the full depth of 936 ft. these did not oscillate enough to cause any difficulty.

To avoid trouble with the permanent guides from the use of expansion bolt fastenings, and to avoid the irregular spacing of bolt holes in the guides if anchor bolts were set in the concrete as it was poured, a novel guide fastener was designed. It was built in the concrete as poured, but still allowed drilling of the bolt holes by templet after the shaft was completed and allowed a leeway for any reasonable irregularity in location while pouring. These fasteners are shown in Fig. 5.

A chart was kept showing the progress made each day by each shift on each part of the work. A large-scale elevation of the whole shaft, stations, tunnels and ore pockets was made, and a certain portion was allotted to excavation, timbering, form work, reinforcing, concreting, etc. To each shift boss was asigned a certain color, and the portion of the chart representing the location and the amount of work done was colored for the shift doing the work. The date was then written through the color. Quantities for this purpose were determined both by actual measurement and by the foremen's reports. For instance, the number of buckets of

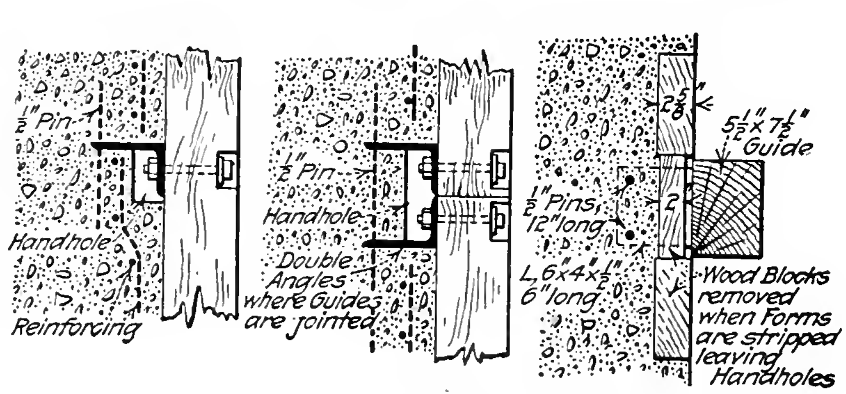

FIG. 5. DETAIL OF NOVEL GUIDE FASTENING

muck hoisted was a close check on the advance in sinking for that shift. The foremen were never formally notified that this chart was being kept, but within two days from the time it was instituted they all seemed familiar with it and watched it closely.

This chart not only furnished information as to progress at all times and gave a comparison of the work accomplished by each shift, but it also served as a record which showed at a glance which shift boss had excavated any part of the work. If faulty workmanship had been discovered it would have been simple to trace it.

Probably the greatest value of the chart, however, lay in the competition it aroused among the shift bosses, who realized that their work was being closely followed and that they were getting due credit.

In spite of the fact that the hardpan through which the shaft was driven is so firm that all former shaft sinking in the district had been done by blasting, it sloughed badly upon exposure to the air, and this without warning. Ground which had been sounded and found solid but a few minutes before would suddenly fall with no warning, so that the sinking combined the difficulties of both hard-rock work and soft, treacherous ground. In spite of this fact, there have been no serious accidents to either construction or the employees during the entire work, which means that while every precaution has been taken to safeguard the men and the work, good luck has also favored the job.

The Foundation Co., of New York City, did this work by contract, under the supervision of its Pacific Coast department, with Bayly Hipkins, vice-president and Pacific Coast manager and A. S. Lilley assistant manager; and under the direct charge of the writer as superintendent, James H. LeFeaver as assistant superintendent and John Sheehy as night superintendent.

Suggests Light Railway Feeder Lines

Light railways of the type used between the main-line railways and trenches during the world war were suggested as having a definite transportation value in sparsely settled countries, in a paper by Charles F. Lang, president of the Lakewood Engineering Co., read before the Pan-American Commercial Congress in Washington. Mr. Lang called attention to the developments in detail design and construction which were brought about by the war use of the narrow-gage railway, with its readily portable track and tie system. He suggested the use of such a railway to supplement the highway and the standard-gage railroad. He said there were a number of places where both the highway and the main-line railway were too expensive to build, particularly in undeveloped stretches of territory. The light railway could be laid out on fairly steep grades with high curvature through undeveloped country with a minimum of earthwork, and there could be in every farm or mine area a personally owned track, each tying up with the through line. He also suggested that in sparsely settled territories which might not warrant the expense for a first-class highway the narrow-gage railway could be used (1) for the construction of a cheaper improved highway which would be sufficient to carry light passenger traffic, and (2) the railway having been used for such construction, it could be used as a railway for the heavier traffic, both the railway and highway together costing less per mile than a hard-surface road would cost now in the United States or Canada.

Important and Neglected Features of Tire Maintenance

Tire Cost and Fuel Cost Are Normally About Equal For Large Trucks—Abuse May Cause Tire Cost to Be Excessive

By A. F. Masury
Chief Engineer, International Motor Company, New York City

Large numbers of persons who use motor trucks—such as contractors—consider that economy, as far as the trucks are concerned, means gasoline saving. However, saving of tire cost is equally important. On a heavy truck the tire cost and fuel cost are about equal. On lighter vehicles tire cost is slightly less than fuel cost, unless pneumatic tires are used, when the tire cost will slightly exceed fuel cost. Why, then, should we hear so much about means of saving gasoline and so little about economizing on tires? While the two items of cost are normally of equal magnitude, abuse of tires can raise their cost out of all proportion to their normal cost, and can swell this item far beyond the utmost extravagance in fuel.

It is a fortunate circumstance that gasoline waste inevitably limits the ability of the vehicle to perform, and that unless the carburetor adjustment is set for reasonable economy the truck will hardly operate at all and consequently cannot consume an excessive amount of gasoline. On the contrary, tire abuse, unfortunately, limits the performance of the vehicle but little, and in addition gives rise to increased chassis maintenance and even increased fuel cost.

Truck owners are often encountered who are extremely particular about carburetor adjustment, who employ the latest air-warming devices, and insist that the engine be shut off at each stop, but they allow the tires to remain cut and slivered, the wheels out of line, and the truck running daily on the car tracks. The truck will actually consume less gasoline without a governor than with one, but the removal of the governor and the consequent overspeeding imposes a heavy toll on tires.

Commonest among tire abuses are overloading, overspeeding, running in car tracks, neglecting cuts and tears, spinning, skidding and sliding the wheels, and wheel misalignment.

Overloading—This stresses the tires beyond their elastic limit, utterly destroying the life of the rubber, and, therefore, the durability and cushioning ability of the tires. Fig. 1 shows a tire which has been over-

FIG. 1. OVERLOADING DESTROYS THE LIFE OF THE RUBBER AND CRACKS THE TIRE

loaded. Note the peripheral crack near the base and the separation of the tire at the base.

Overspeeding—Even with a light load, overspeeding has the same effect as overloading, since the increased speed causes the impact of the tire on road bumps to be magnified. Running over a bump at twice the normal speed pounds the tire eight times as hard, and consequently may overload it at one spot 400%. A tire treated in this manner may be seen in Fig. 2. If high speed is necessary, pneumatic tires should be used, though they cost more; it will be much cheaper than putting solid tires in the condition shown, after a few hundred miles.

Running in Car Tracks—This simply cuts the tires by centering the pressure at one point instead of evenly over the treads. A tire which has been run in car tracks is shown in Fig. 3. The edges of the rails, particularly the guard flanges of street-car tracks, become sharpened by the friction of the car wheels. Running tires over them is much like running them over the edges of steel knives.

When solid tires are cut or torn by glass or sharp stones the rubber slivers. These slivers should be cut off as soon as they appear. Care should be taken that a clean notch just below the end of the tear is made. If the sliver is left on, it will contribute nothing to the strength of the tire but will continue to extend until half the tread width is torn loose. Fig. 4 shows the condition produced in a tire by allowing slivers to remain uncut.

Spinning, Sliding and Skidding—Spinning and sliding the tires in starting and stopping, and skidding in rounding curves, also leaves serious destructive effects similar to that shown in Fig. 4. Upon loss of traction most drivers will speed up their engines under the wrong impression that this will increase traction. Actually, it does the reverse. The more slowly a wheel turns the better traction it has, the more gently it is started turning, the less liable it is to slip. When a wheel begins to lose traction the driver should throttle the engine rather than speed it up, retarding his spark and being ready to release the clutch to prevent stalling. In engaging the clutch it is also well to let it in gently, and low gear should be used, as this will permit the wheels to turn very slowly without so much danger of stalling.

In the application of the brakes the wheels should not slide. Not only does sliding the wheels injure tires, but it reduces the braking effect. The quickest stop is made when the wheels are just turning and the abrasion of the tires is least. Skidding on rounding curves is as unnecessary as it is dangerous. It is due to turning at excessive speed. All of these abuses do untold harm to the tires. A tire is made to roll over the ground, not to slide.

FIGS. 2 TO 5. CONDITIONS RESULTING FROM VARIOUS ABUSES OF SOLID RUBBER MOTOR-TRUCK TIRES
Fig. 2. Overspeeding. Fig. 3. Running in car tracks. Fig. 4. Neglecting slivers, skidding and sliding. Fig. 5. Misalignment of wheels.

Besides these more obvious causes of excessive tire wear, there is an insidious cause which is too apt to be overlooked. This is faulty alignment. When the tire rolls smoothly there is a minimum of wear, but if out of alignment, it has a combination rolling and sliding movement over the road which not only causes rapid wear but consumes power. There are two forms of faulty alignment; that in which the wheel itself is out of line, so that it wobbles, and that in which the wheel spindle is at an improper angle, so that the wheel is constrained to a position out of parallel with the direction of the vehicle's motion.

Wheel wobbling is caused by warping of the wood and strains. Some of the strains which get wheels out of true can be avoided. When a truck is driven diagonally into the curb, for instance, or when a corner is rounded too sharply or a boulder is struck a glancing blow, the severe lateral strain at one point of the circumference of the wheel is apt to warp it. Sometimes carelessness in applying or removing pressed-on tires warps the wheel, and in some cases a careless operator

will press the tire on crooked, so that the effect on the tire is the same as that of a warped wheel. The remedy is to have the tire pressed off and the wheel trued.

Misalignment of the wheel spindles is due to excessive shocks, such as running into curbs, overspeeding on rough roads, and so on, which bend the axle or the steering arms of the front steering knuckles. The destructive effect of a slight misalignment can readily be appreciated when one realizes that if a wheel is only out of line one degree horizontally it must slip 92½ ft. sidewise in a mile of travel. The destructive effect upon the tire is the same as though the truck were pulled sidewise this distance by a winch. On the periphery of the tire one degree is only equal to about $\frac{9}{32}$ inch.

Alignment of wheels can only be made true by accurately checking the distance between the wheel felloes. There are several good methods of doing this, and a number of methods that are not so good.

Most motor trucks have their rear wheels exactly parallel. To test their alignment, the simplest method requires two men and a tape. The end of the tape is held against the front of the inside space on one rear wheel, and the tape stretched across the corresponding point on the opposite wheel, care being taken to have the tape level and stretched tight. The bottom points of the felloes are then checked, and then the rear points. All three of these measurements should be the same. The most common misalignment of the rear wheels is what is called a spraddle. By this is meant that the bottoms of the wheels are farther apart than the top. If this condition is found, the wheel bearings should be inspected for looseness first. If these are properly adjusted, then the axles should be straightened.

Front wheels should not be parallel. For greater strength and easier steering they are cambered; that is, the wheels are farther apart at their tops than at their bottoms. To correct the resulting tendency for them to roll incorrectly they are correspondingly gathered so that their fronts are drawn or toed-in, usually about ⅜ in. Measuring as before, correctly aligned wheels will have their bottoms and their fronts about the same distance apart; the bottoms may be ⅛ in. closer together than the fronts, but should not be farther apart than the fronts.

If these measurements do not check, the gather at the front may be adjusted by means of the tie-rod, which is threaded for adjustment. Before adjusting the tie-rod, however, it would be well to be sure that the steering arms have not been bent. This can be determined by measuring the distance from the ball or pin, as the case may be, to the wheel felloes. The two arms should be the same distance from their respective wheels. If they are unequal, the one that is bent should be straightened, until the distance is the same, and the final adjustment made on the tie-rod.

So far, these checks apply only to the relation of the wheels to each other. Another important check must be made on the alignment of the axles with the frame. Naturally, the axles should be perpendicular to the chassis center line. This can best be checked by selecting a fixed point at the center of the axle, such as the front universal, and checking the measurements from it to the nearest unobstructed point on each rear wheel. The two should be equal. If unequal, be sure that the truck is on level ground and that the two rear springs are deflected equally. This may be checked by measuring the distance from the bottom of each frame side rail to the axle. If unequal, a jack may be used to raise the low side of the axle to the same level as the other side. The measurement to the universal can then be repeated. If it is found to be still unequal, the cause will be found either in unequal radius-rod adjustment, or, if no radius rods are fitted, in loose axle spring-clips which have permitted the springs to shift. At the front a similar check may be made from some central point on the crank case to the opposite point on the wheels.

Too many motor truck users neglect to check their wheel alignment until the occurrence of an accident or other cause that necessitates a serious repair. Misalignment is apt to result from minor causes in daily service, and unless frequently checked may go unnoticed, bringing about excessive tire destruction without apparent cause. A tire which has been damaged by misalignment is seen in Fig. 5.

Poor Filter Operation Accountable for Typhoid Outbreaks

Overworked Filters in Moline, Ill., Lead to Bypassing Nonsterilized Raw Water to Clear-Water Basin

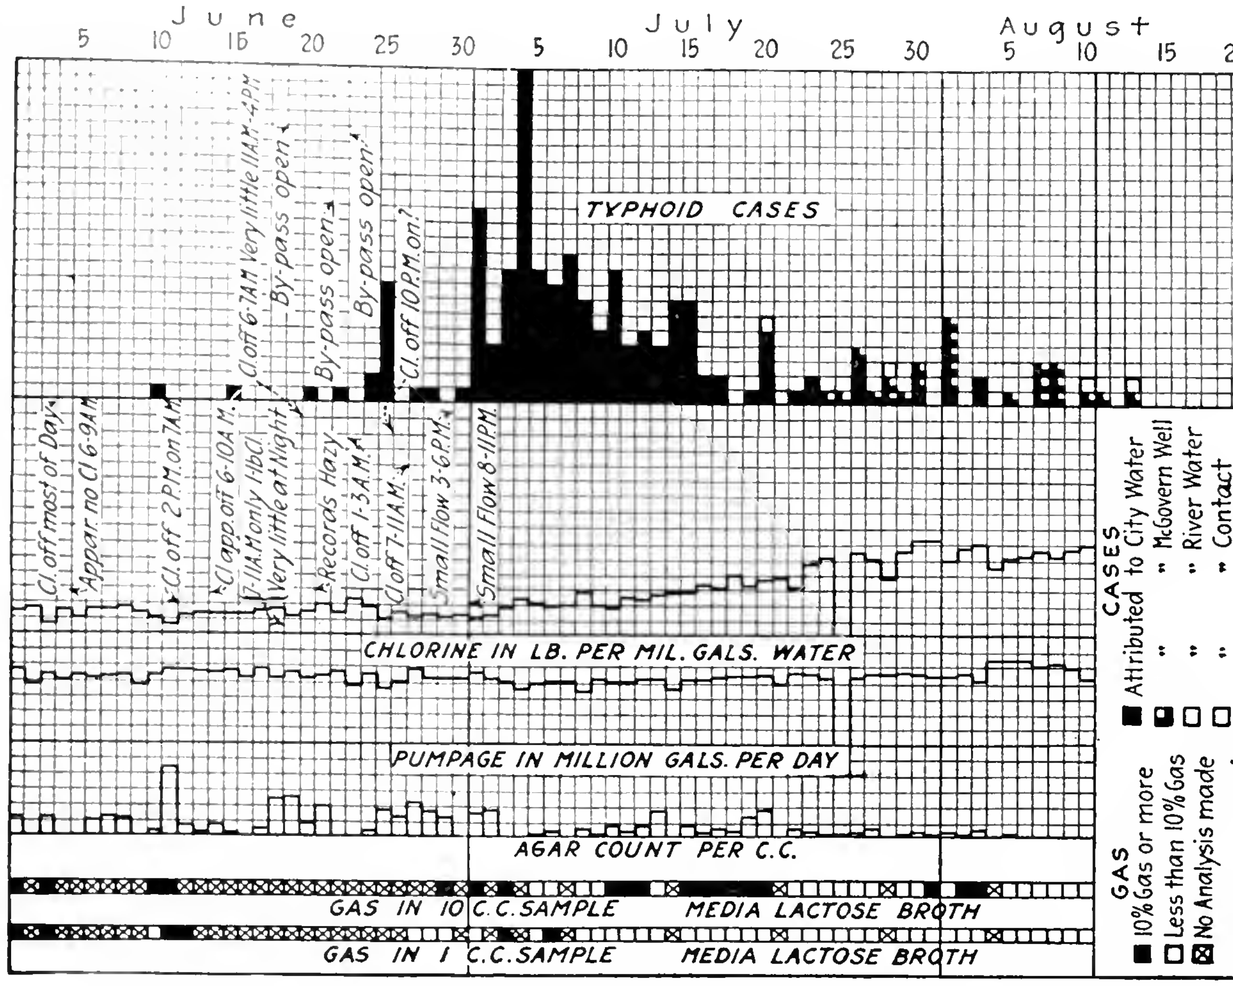
UNFILTERED water bypassed to a filtered-water basin in Moline, Ill., during the past two years has cost many lives and has caused not a little sickness. Clogged underdrains, insufficient capacity and indifferent chlorination of an unfiltered or improperly filtered supply are the links in the chain of typhoid carriage by which typhoid outbreaks have occurred in a town nominally supplied by a potable, safe water, despite newspaper boil-the-water advertisements to the contrary. Two exhaustive reports on the situation have been made by the Illinois State Board of Health. The first, dated February, 1918, went thoroughly into the series of outbreaks which occurred in the autumn and winter of 1917 and indicated that there were many interruptions in the chlorination of an inefficiently filtered and unsafe water. Typhoid in cities discharging into the river from three to 35 miles above the intake was held largely responsible for the infection of the raw river water. The second report took up a later outbreak traced to the opening of a bypass valve in June, 1918.

In 1902, Moline installed a mechanical filtration plant providing space for five 1,000,000-gal. units, but only three were equipped until 1910. An original 30-in. bed of sand overlying 14 in. of gravel was reduced to 20 in. in 1918. A large portion of the underdrainage system had become clogged, and only portions of the bed could be washed; thus the rate through the washed portions was increased excessively. Bacterial efficiencies of the plant ranged from 35 to 96 per cent., averaging 70 per cent. Due also to the clogging, the quantity filtered was insufficient, and water on the surface of the filters was bypassed directly to the filtered-water basin. This was made possible by the insertion of a valve below the junction of the wash-water outlet and effluent-to-drain outlet as shown in the sketch. The report states:

> Judging from the rather frequent use of the bypass, it appears certain that altogether too much confidence has been placed in the chlorinator, and far too little attention has been given to the filters.

Mechanical devices will sooner or later give some trouble, and the chlorinator installed at Moline was no exception, for it has balked on a number of occasions. It is only to be expected, therefore, that with the filters operating with very low efficiencies, with the water bypassed at times and the chlorine off at spells, that the water-supply must have been of a quantity at times which would menace the health of the consumers.

However, the defects of the filter plant and chlorine machine, and the dangers due to using the by-pass appear to have been reported by the operator to the city authorities at different times during the winter of 1917-18, while the public was warned by newspaper advertisements from Feb. 15 to July 2 that the water was unsafe.



CONDEMNATORY RECORDS PREVIOUS TO EXPLOSIVE TYPHOID OUTBREAKS

In July, 1918, the State Board of Health was called in again to investigate further outbreaks. Although the filter plant had been partially overhauled following the winter outbreak the investigation practically eliminated, as before, all sources of infection but the water.

Quoting again from the report:

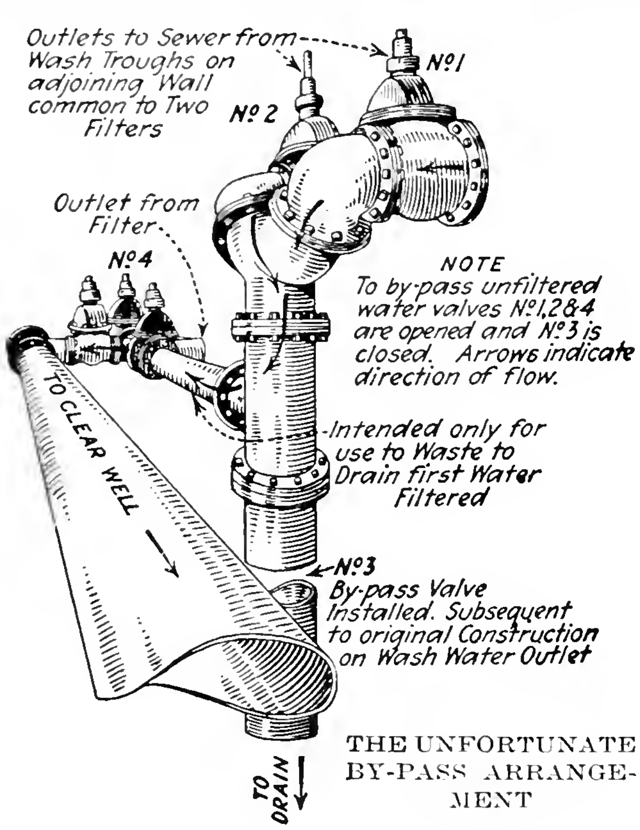
It appeared quite impossible, therefore, that so large and explosive an outbreak (see chart) could result from water which had passed through the filters, even should the chlorine used for disinfection have been turned off for some reason. It appeared so evident, however, from the investigation that the water was the source of infection that it was only natural to suspect that the bypass had been opened at some time or other. . . The raw water during a portion of this time had been passed through but one of the settling basins, as the other basin was being washed during the night. Even the settled water entering the filters and the bypass was, therefore, of inferior quality.

It was found that both on June 19 and again on June 22, during the periods the bypass was open, no chlorine was being added for considerable periods, and very small quantities the remainder of the time, due to trouble in the chlorinating apparatus.

Following the main outbreak, reports of an unwarranted number of cases continued. A study made of this situation showed that a well extending almost wholly in limestone located at 352 Eighth St. had become infected through the entrance of sewage from near-by sewers and a number of people received their infections here.

The board declares unqualifiedly that the bypass is a dangerous arrangement which should be removed at the earliest possible date. For the time being, until additional filters are installed or additional storage capacity for filtered water is afforded, the bypass might be retained, but should be fastened shut by means of a lock and chain and the key left with one of the head men at the plant. This bypass should then be opened only in the event of an emergency, and only with a very heavy and continuous flow of chlorine being applied to the water. The bypass has already caused Moline citizens sufficient trouble, and it should not be permitted under any circumstances to repeat the past performance.

Connections between manufacturers' and city mains were under suspicion, and tests indicated that the single check valves tested were not always effective, but the general spread of the outbreak over the whole town practically eliminated the dual system. The practice was condemned, however, by the board. The investigation



THE UNFORTUNATE BY-PASS ARRANGEMENT

was made under the direct supervision of M. C. Sjoblom, then acting chief engineer for the Illinois State Board of Health.

The Long Beach Sewage Screen; A Correction

In the article on the sewage screen at Long Beach, Calif., published in *Engineering News-Record* of May 22, 1919, p. 1012, the names W. J. Knowlton and J. W. Geeks should have read W. T. Knowlton and J. W. Cooke. On p. 1013, in the same article, the dates Jan. 3 and 4, 1918, should have been June 3 and 4.

Bettering Concrete by a New Mixing Method

Using as a Basis Motion Mixture Studies of Concrete in the Mixing, New Type of Mixer Is Developed In Which, It Is Claimed, Cement Gets Necessary Thorough Contact With Aggregate

By Nathan C. Johnson
Consulting Engineer, New York City

This is a part of a lecture entitled "Better Concrete; the Problem and Its Solution," delivered recently by Mr. Johnson before the Philadelphia Engineers' Club. The lecture was much longer and contained a number of motion pictures of concrete during the mixing and setting processes. These pictures were taken with a special camera with an automatic long-interval shutter, so that the views reproduce on the screen, in a few moments, natural processes taking many hours or days—Editor.

Since the majority of the units entering into concrete are minute, they may be virtually affected in whole or in part by things minute, although collectively of great importance. It may even prove on examination that what to the eye are tiny crazings, of questionable import, may be vast chasms relative to the size of a cement grain put into the mass as a medium for transferring stress from sand grain to sand grain and that they may interpose impossible barriers to its functioning. Single air voids not uncommonly bulk larger than a dozen or more sand particles; and air voids are known to be present in vast numbers. Water pockets by the thousands in a single yard of concrete may cut off certain other would-be workers by the hundreds of thousands, and even sizable stones.

To estimate the true significance of such possibilities it may be well to place in diagrammatic form, as a preface to deeper study, the family tree of concrete. (See Fig. 1.) First and foremost in importance is the "glue" formed by the union of the powdered cement of

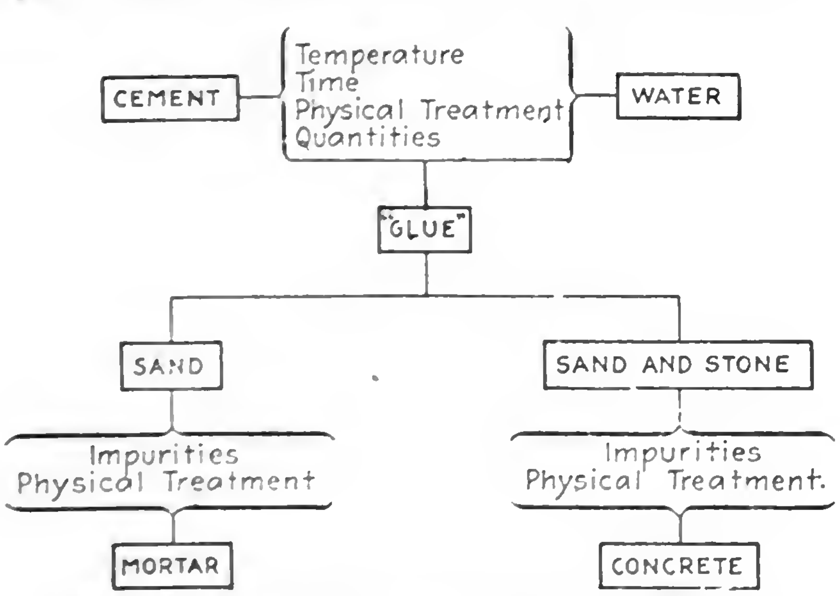


FIG. 1. GENEALOGICAL CHART OF CONCRETE AND MORTAR

commerce with water. As this formation is a chemical reaction, it follows the laws of such reactions and is affected vitally by two variables, temperature and time. The first is particularly difficult of regulation in field operations, but the second—as well as a third variable, physical treatment—may be controlled. Obviously, also, the strength of the fluid cementing solution so produced will depend primarily upon relative quantities of the two reacting substances. To the "glue" thus formed, which has greater or less worth according to the values of the variables affecting its formation, sand is added to make mortar, or sand and stone to make concrete—with, in each case, impurities, such as air, or other contaminating substances, and, again, physical treatment, entering as factors qualifying ultimate value.

If cement were supplied as ground after burning in kilns, it would be so hungry for water that reaction with mixing water would take place too quickly; and to avoid this, manufacturers add gypsum, which is hydrous or water-bearing calcium sulphate, to the still hot cement. This heat drives off water from the gypsum; and this water, spreading as steam, reacts with the hungry cement particles, forming over their surface a very thin, protecting skin of dead or hydrated cement, which for a time—depending upon the thickness of this skin and the temperature—resists penetration of mixing water to the active material within, deferring reaction to give ease in handling. It follows, therefore, that little of this chemical action has taken place before concrete is placed in forms.

Such a protective skin is pictured in the photomicrograph, Fig. 2, about an inert cement grain found in concrete. Obviously, it should be advantageous to remove this dead skin in some way when ready to use cement, so that water might find access without delay and make more and stronger "glue" in the brief hour or two of freedom before setting takes place. Of course, we must coat sand and stone with cement. Yet reason tells us that even an infinite supply of cement particles can cover a sand particle only so far as they may touch it at tangent points, while a solid bedment is assumed and desired in concrete. If there is not an infinite supply of cement particles, even this tangent covering is not possible.

Furthermore, when cement particles, sand particles and pieces of stone are wet, an envelope of water covers them, preventing contact, except accidentally, even at points of tangency, as shown in the diagram, Fig. 3, traced from the photograph, Fig. 2. This explains why there is rarely, if ever, contact between particles as their relative positions are revealed in magnified photographs.

A little thought and calculation with regard to aggregates reveal certain other facts not often considered. Briefly, these are that in a cubic yard of 1:2:4 concrete there are about one million stone particles, up to and including $1\frac{1}{2}$; that there are about 25 *billion* sand particles with a commercial coarse sand, or 200 billion particles with a very fine sand, all of which have to be distributed and wetted and mixed with some 200 to 300 billion cement particles in a space of time that will pay commercially—usually less than a minute. Evidently, since this is so, "covering" sand and stone with powdered cement would really mean that when using coarse sands there would be not to exceed four to six cement particles; and using fine sands, not to exceed 1 to $1\frac{1}{2}$ cement particles for each piece, large or small. Covering should be actual and thorough and uniform, but, obviously, true covering can only come through spreading of a liquid cementing product; and to achieve even

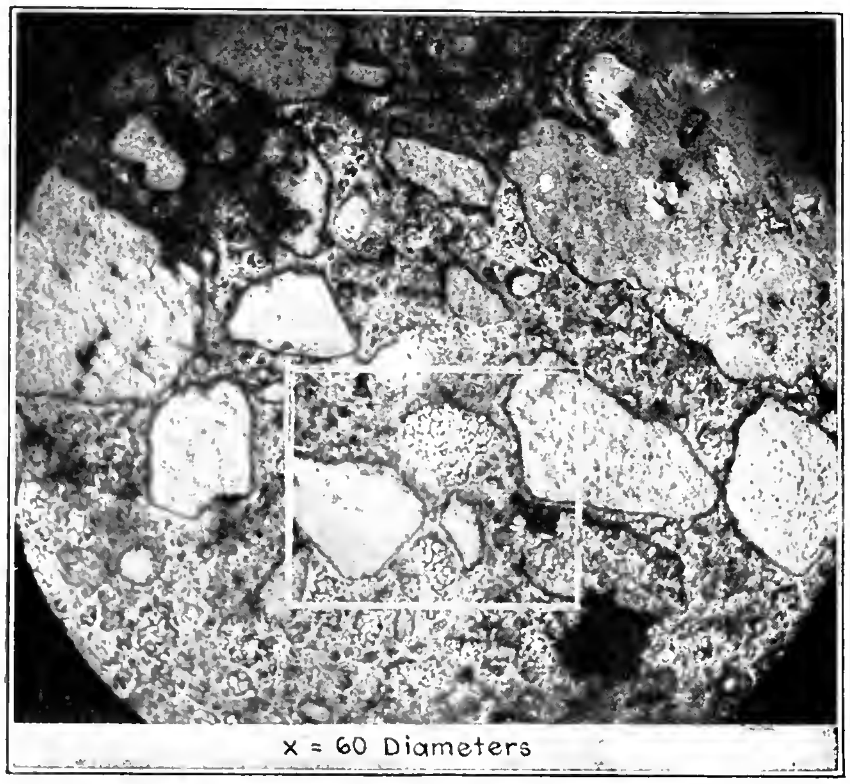

FIG. 2. PHOTOMICROGRAPHS OF COMMERCIAL CONCRETE SHOWING SAND GRAINS, UNUSED CEMENT AND AIR VOIDS

The view at left is an enlargement of the section limited by lines on the right view

a fair result, there must be left no analogue to the "unstirred sugar" of a cup of coffee, else some billions of potential workers will be rendered idle through denial of means wherewith to do their appointed share of work.

Remembering these things, further light may be gained by reconstructing the processes that formed a representative concrete, now in existence. Concrete from the warehouse of the Naumkeag Steam Cotton Co.'s warehouse at Lynn, Mass., is shown in Fig. 2, magnified 60 diameters. In it are clearly visible the sectioned sand grains with their irregular outlines; the clear matrix of hydrated cement; a few voids; and some "unstirred sugar" in the form of unhydrated cement particles. In Fig. 2 is also shown the lower center of the same field, enlarged to 180 diameters. It is to be remembered that in each of these photographs the relative positions held by the several substances are the positions held by them when placed in forms and that must be held by them so long as the concrete endues. What happened when this relationship was first established? All cement particles in the vicinity doubtless reacted with water, rather quickly for some time after the protecting skin was pierced. During this interval the sand grains lay surrounded by water, waiting quietly whatever might happen, save, perhaps, for an occasional settlement to easier position as concrete deposited above increased the general pressure.

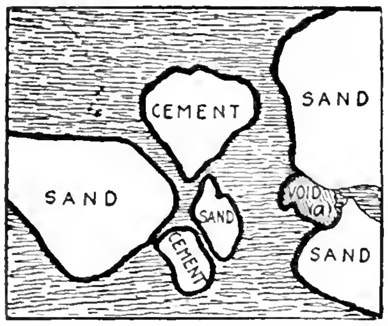

FIG. 3. PART OF FIG. 2

Showing relation held by cement and sand particles and water when placed in forms

At the surface of cement particles, however, there was, at first, saturation of the hydrated skin; then spasmodic reactions as water first reached active cement, formed new products, became sated and gradually diffused; then renewed activity as new water reached deeper layers of active cement through the same agencies, with repetition of the processes until setting of the richest products *directly at the surfaces of the cement particles* formed a new protective skin and brought about a shut-down of hydration.

The water-filled space about cement and sand particles was, during this time, gradually becoming charged by diffusion with these cementing products. But, diffusion is slow; and as distance from the source increased, concentration of these products became less, being *least* at the surface of the sand particles, where for man's purposes, it should have been *greatest*. If diffusion could have been aided by stirring, this defect would have been overcome; and, furthermore, longer activity of the cement particle would have been possible through removal of those surcharged products at its surface (where richness was not desired) and supplying of fresh water. Surely, one way of improving concrete should lie in procuring by some means a greater concentration of cementing products and distributing these, instead of insulating and diluting water, over the sand and stone *before* they find their final position in forms. If this were done, "water voids"—spaces left by water uncharged with cementing products—would disappear, for there would then be no uncharged water and the nature of such charging products is to solidify.

One other feature is prominent in these photographs; namely, an air void (recognized by its spherical or spheroidal form) tucked away at a surface pocket in a sand grain. When this grain was first wetted, this pocket was, of course, filled with air; and before the air could escape the viscous water envelope went over it, imprisoning it by surface tension; and, as diffusion progressed, molding it for all time in solidified cement.

By optical examination, boulders and sand grains of all sizes are found to have similar surfaces, full of pits and seams which are admirable for attachment of cement if contact could be brought about, but potent for ill unless inclusion of air bells is prevented. If only some means, such as stirring or scrubbing, could be utilized to remove impurities such as air, considerable improvement in general quality should result, for although one void is very minute, its duplication billions of times must be of great importance.

Although the mind sees in increasing number other possibilities indicated by reasoning as probable means of bettering concrete, those cited have every element necessary for very substantial improvement, provided they can be put into effect.

Starting experimentally with studies of the chemical union of cement and water, it is found that the process is initially of much greater rapidity at elevated temperatures. In Fig. 4, for instance, are shown interlacing crystal formations at 70° F. after three hours, as contrasted with those at 50° F. after 10 hours. As the latter photographs show no visible change from their original appearance, temperature is evidently of great assistance in forming concentrated products.

It is further to be noted from these photographs that there is grouping together of individual particles, with less intense formation of cementing products at the boundaries of such groups than at single particles. If such grouping were to exist in concrete, much of the cement would be taken from points where it should be usefully applied, since hydration would soon begin to act to unite these groups inseparably. But since these groupings are always observed, such deprivation doubtless does take place, with resultant effect on the concrete. Furthermore, examination of commercial powdered cement reveals small aggregations present in infinite number, due possibly to hydration from moist air and sticking together before it reaches a user's hands. Evidently such groupings should be forcibly broken up either prior to or during mixing, and evidently, also, there is little use in finer grinding of cement unless such groups can be broken up.

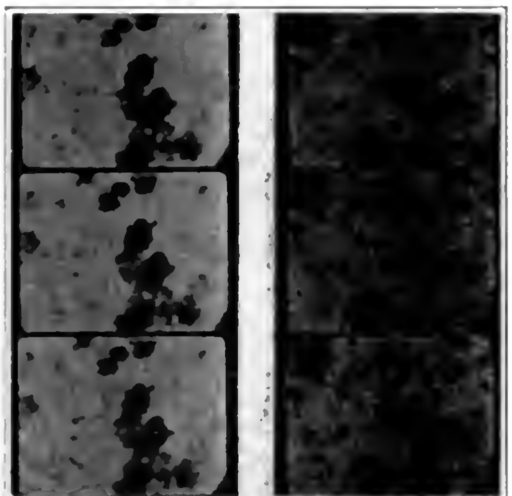

FIG. 4. HYDRATION OF PORTLAND CEMENT. CAMERA INTERVALS, 5 MINUTES

Grouping of cement particles rendering futile fine grinding

In addition to elevation of temperature, it is also found that intensive hydration can be brought about by violently stirring cement for periods longer than are usually employed, much as stirring sugar increases the sweetness of a cup of coffee. And it is further found that while sand grains poured into water are lifted bodily by tenacious air bells resident at irregularities in their surfaces, such air bells can be removed and full contacting of water (or of cementing solutions) brought about not by stirring alone, but by such violent stirring as to cause the attrition of particle on particle sufficient to bring about a scrubbing action. Considering these two phenomena in analogy, it is not improbable that the increased hydration of cement brought about by violent stirring is due to a removal of the protective skin from individual particles through such interparticle attrition, bringing about earlier and more prolonged chemical activity, as well as through the forcible breaking up of minute groupings before noted.

Combining these two benefits of removal of tenacious impurities and increased hydration by violently stirring cement and sand together in water, there is every element present of an improved process of making concrete, particularly as such violent stirring raises by internal friction the temperature of the mass, with further increase of hydration.

But what is the actual effect and result of this as expressed in accomplishment? Aside from increased hydration products as noted by the microscope, there is formed a viscous, coherent mixture, not inclined to separate even though very plastic, with little or no formation at the surface of fluffy "laitance." Remembering the levitation of sand grains in water by attached air bubbles, as well as the lubricative effect due to the mobility of gaseous bubbles in a liquid, it is not improbable that removal of such bubbles, together with the heavier specific gravity of the fluid brought about through increased solution of cement, has overcome the tendency to segregation usually present. Furthermore, it is at once evident that if increase of hydration can be assured, greater tolerance in the percentage presence of water is permissible, with increase of plasticity and ease of working, and, at the same time, assurance of a satisfactory result. Elimination of laitance and segregation on commercial operations would be of utmost importance, for materials so separated are almost valueless of themselves but would have high value if retained in their proper places.

And a corollary effect should be better compacting and greater solidity of the mass, with commensurate strength and endurance. If the particles shown in Fig. 2 had been closer together, solutions of cementing products at the surfaces of sand grains would have been stronger, through nearness to the source. Furthermore, a greater number of strong sand grains would have been present in any given volume. This result is sought in commercial work by spading, tamping or rolling, the last named being found by study to be preferable where the form of construction, as in roadways, permits of its use. Yet, if increased hydration is realized, together with very thorough distribution of such hydration products and detachment of air bubbles from sand and stone, a minimum of such artificial compacting is found to be necessary for a substantial improvement in texture and strength.

Furthermore, there should be less likelihood of points of weakness developing in such a product, either through the presence of an impurity at a center of disintegration or through loss of uncharged water, or through unequal internal strain due to nonuniformity. Study confirms this reasoning, for mortars (stuccos) and concretes reveal that three-branched cracks and their later ramifications are of primary origin, occurring at or about the time of set; and that they are induced by lack of uniform internal strength, for rupture comes suddenly, much as a sheet of paper might find relief from unbearable strain by rupturing abruptly about some point of weakness. (See Fig. 5.)

And, not least, disintegrations and softenings should, with such material, be at least mitigated, if not fully done away with. Disintegrations result from entrance of water into the body of concrete. Sea water carries so little material capable of attacking concrete that the entrance of many millions of gallons into the concrete is necessary for effective attack on a single cubic yard. Nor is the action of fresh water substantially different; and with this fluid the same requirement applies. As

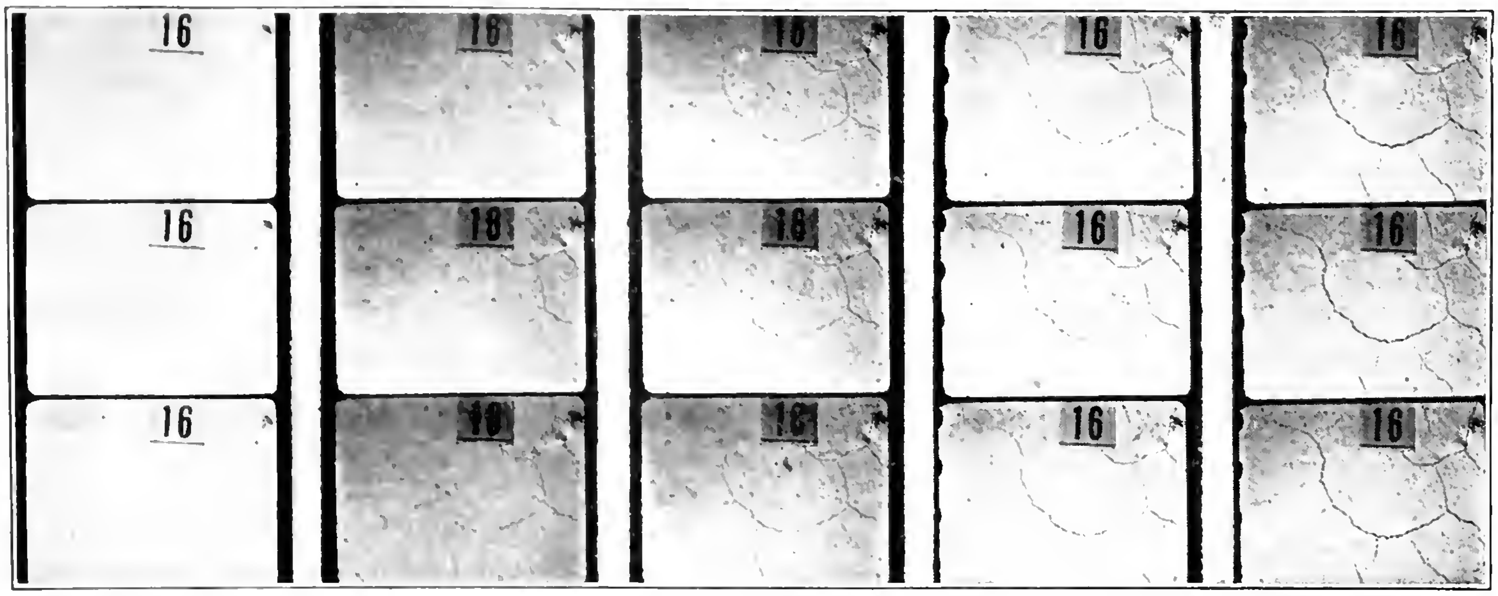

FIG. 5. FORMATION OF THREE-BRANCHED CRACKS IN STUCCO CAUGHT BY MOVIE CAMERA AT ONE-SECOND INTERVALS

Note that these originate at the surface pit seen in the upper right-hand corner

for rupture by rusting of reinforcement, the existence of this fault argues conclusively that water has reached the steel through the concrete, but when that happens, rusting, with expansion and rupture, is to be expected. On the other hand, given a uniform, dense concrete, without water or air voids, or laitance seams, or shrinkage cracks, the seas and lakes and rivers must confine their efforts to surfaces, instead of finding ready access to the interior, with proportionate endurance.

FIG. 6. FIRST CENTRIFUGAL CONCRETE-MIXING MACHINE IN ACTION. 10-INCH DIAMETER BOWL

But however much laboratory experimentation may prove, conversion into commercial terms only will be of substantial benefit.

Early in this effort, existing forms of mixers were discarded as ineffective and not susceptible of necessary changes. With time ever a limitation, the first thought was to substitute rapidity of action for customary slowness. By the same agency, also, it was hoped to effect the violence that seemed to be necessary to force reluctant materials into proper usefulness. In addition to rapidity of action, repetitive cycles and a mass held compactly together to secure interparticle attrition were indicated. These constituted a new and different process from that heretofore used and demanded new means to effect it.

High rotative speeds imply centrifugal force as a concomitant. Centrifugal force would hold the mass of materials together, but would render inactive the usual drum mixer. Furthermore, a very small portion of available drum space in such machines is in active use, the overcapacity varying from 250% to 825% of the batch size in the products of 10 different manufacturers. It was also found that much useful mixing time was consumed in charging and discharging, batches having to enter and leave through severely constricted openings.

The expedient was adopted, therefore, of using an open bowl, rotated rather rapidly in a vertical axis. Centrifugal force would compact the rotating batch in the bowl and cause it to rise toward the top. At proper points, curved blades could cut off ribbons of material, diverting them to the center, so that repetitive cycles could be brought about. Discharge could be overside by utilizing the velocity of the mass, giving a high dis-

FIG. 7. THREE-CUBIC-FOOT CENTRIFUGAL MIXER IN ACTION

charge, while the full diameter of the bowl would be available for charging, doing away with the high elevation of material necessary to make it pass through a constricted spout. Furthermore, both mechanism and mass would be open at all times to observation. [The type of mixer here described is covered by patents—EDITOR.]

The first mixer held 30 lb. of material and was improvised from an iron potato kettle with an iron tamper for a base, the bowl being rotated through one set of gears by a ¼-hp. motor which once operated an adding machine (See Fig. 6.) Diverting blades supported by small pedestals overside completed the mechanism. Strangely enough, it was successful almost from the first; and results obtained with it were so interesting that larger units were undertaken. A 3-cu.ft. machine was then constructed (Fig. 7) and later, a ½-yd. machine. Trials and tribulations were not few in number, but they are of no import in this discussion. Suffice it to say that a most intense action was secured, showing in practical result the actuality of the theoretical needs indicated by the reasoning before set forth.

Colonel Parsons' Address to His Men

ENGINEERS will appreciate the following heartfelt words by Col. William Barclay Parsons, now printed in the *Fighting Engineer*, the publication of the Eleventh Engineers' Association. It was delivered on the occasion of the regimental dinner at Hotel Pennsylvania in New York on April 30:

My men. I do not say officers and men, but, simply, my men. This is probably the only opportunity that I shall have to say a word to you all collectively.

In a few hours the process of disintegration will begin, and in a few days this regiment will exist in history only and the close comradeship that has held us for nearly two years will be at an end.

You and I have been together during that time, we have marched together by day and by night, we have worked and fought together in sunshine and in storm, in heat and in cold. We have been together and have seen our comrades fall, not to rise again, and we have stood side by side, with heads uncovered, as we laid them to rest in the far-away soil of France. Such a comradeship cannot be broken without a pulling of the heart strings. As you go on your several ways you will take with you my ever-abiding affection, and I hope that you are leaving me yours.

There are a few things that I ask you never to forget: First, and above all, the record of our regiment. That record, without a stain, without a spot, is yours. You made it, it is now yours to keep. In life let it be an inspiration to you, and when moments of temptation come, as they will come to all of us, let us remember that we belonged to the Eleventh, with its record second to none, and that it is the part of each one of us to live up to that record. You were willing to die for it; are you now willing to live for it?

It is right that men should make every effort, as men in Paris are now doing, to prevent war, but don't fool yourselves that there will be no more wars. Just so long as men are men, there will be wars and you will be called upon again. Unless the next war comes very soon, I fear that the operation of time will cut me out and it will be a younger and better man who will lead you on. For him, the best that I can ask is that you will give him the same loyal and faithful support that you have given me.

But while waiting for the next war of arms, remember there is always going on the war of good citizenship. In the war just ending you have done your duty; in the days to follow there is still a duty to perform. In your hands you have held the rifle and the pick, the weapons of the engineer; now you hold in your hands the ballot, the weapon of a good citizen. Use the latter as you have used the former, in the service of your country, and insist, as members of the Eleventh Engineers, on the highest ideals of law, order, decency, liberty and fair dealings to all men.

I cannot at this moment shake the hand of each of you, but, before we separate in the next few days, I hope that every one of you will come to me and let me give you a parting clasp. May God bless you, men, and keep you and give you, each and every one, all health, strength, happiness and success. May you triumph in the battles of life, and having gained that victory enjoy the peace that passeth all understanding.

Railway Bridge Design Loadings and Actual Engine Loads

Moment and Shear Curves for Engines of New York Central Lines West—The Question of Minimum Loading

BY B. R. LEFFLER

Bridge Engineer, New York Central Lines West of Buffalo, Cleveland, Ohio

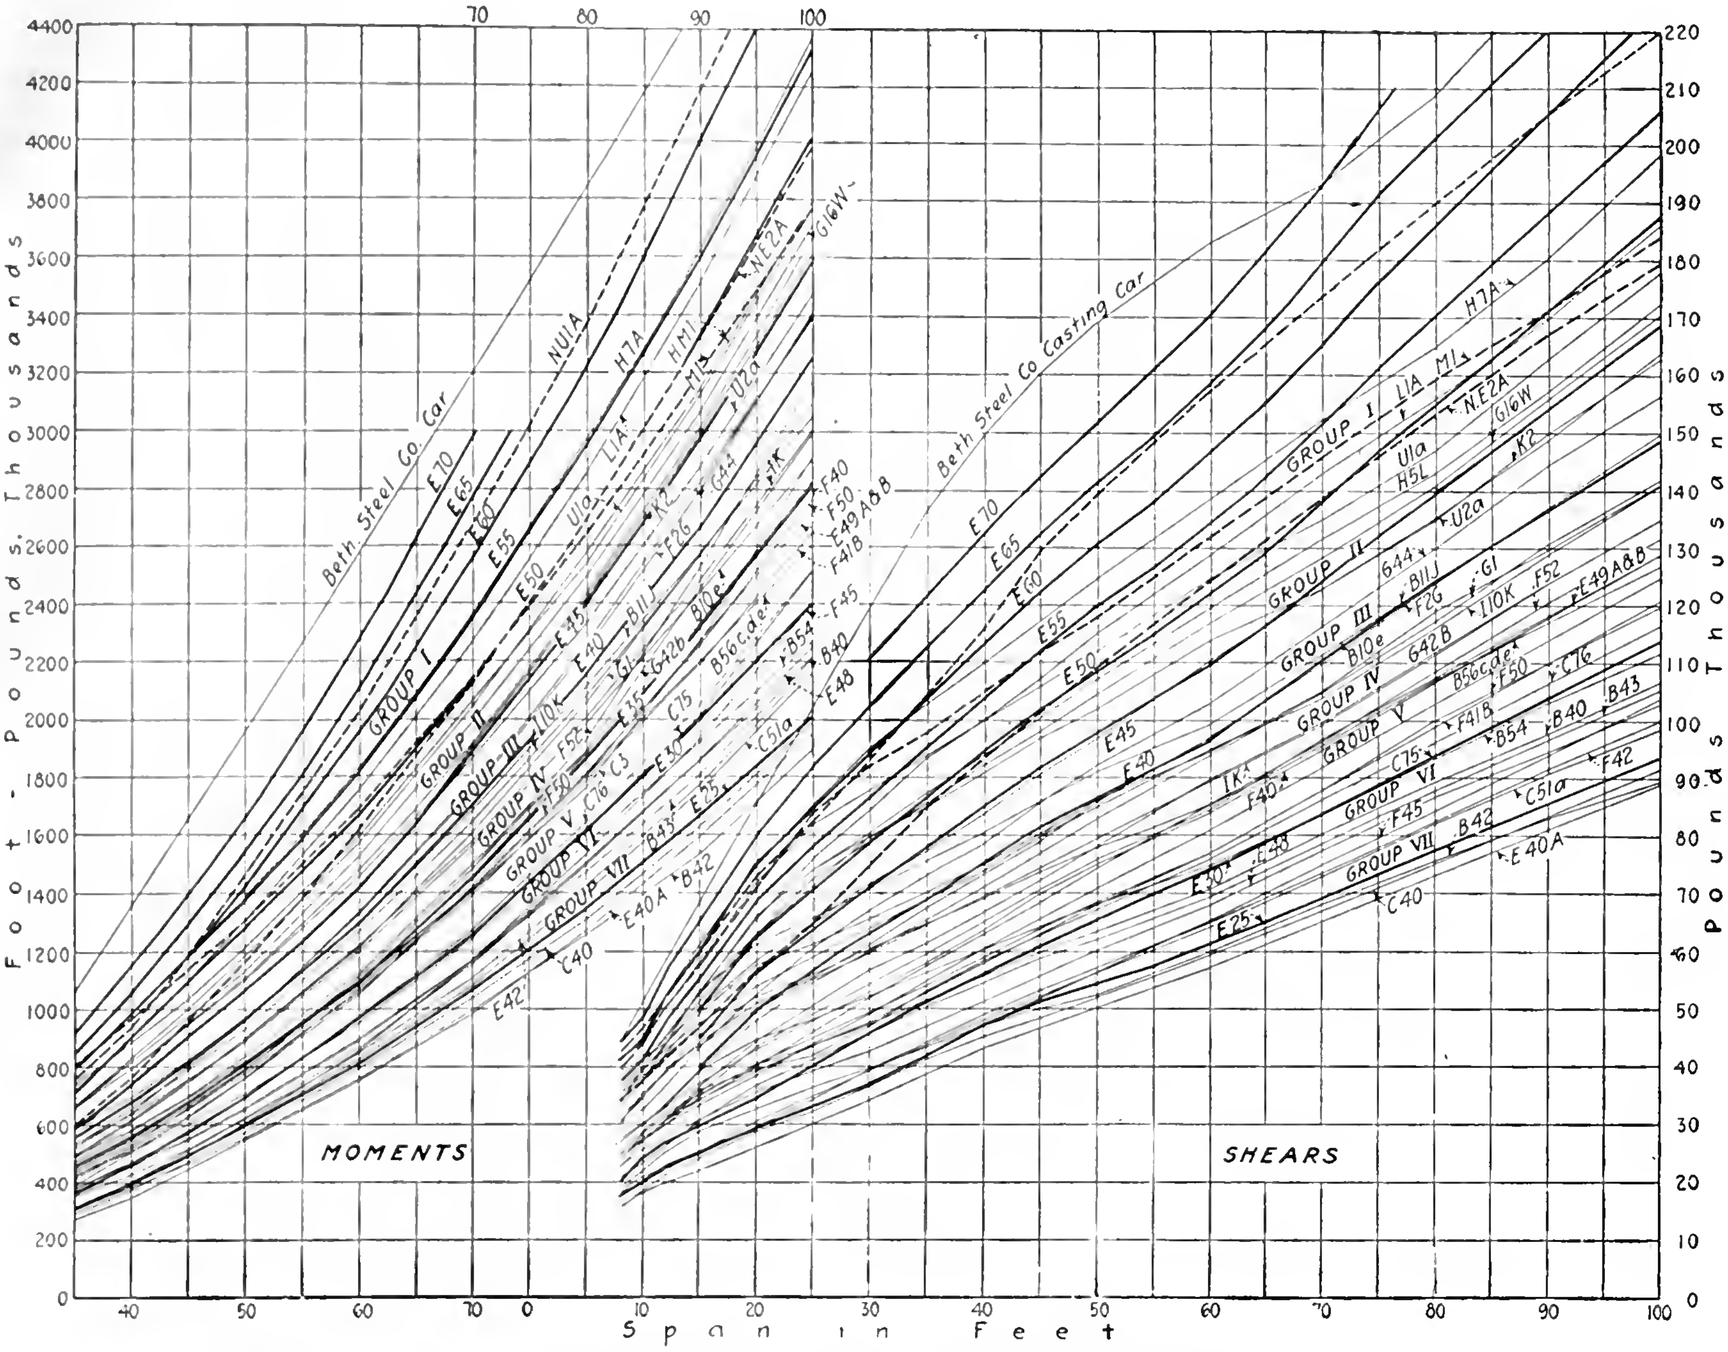
DEVELOPMENTS in railroad practice during recent years have carried engine and train weights slowly but steadily higher, until the margin between actual loads and current bridge-design loadings has become quite small. Recently, at the American Railway Engineering Association convention, remarks made in discussion of the subject of bridge specifications seemed to show a faith on the part of some that present design loadings afford a sufficient margin to last for a long time. However, an analysis of the bridge effect of engines operating on the New York Central Lines West shows that the heaviest power is very nearly up to the design loading in use today, and that special loads go even higher.

As summarized on the diagram herewith, showing moment and shear curves for spans up to 100 ft. under the various engines in use on the road, the actual loads are fairly well distributed over the range between E25 and E65. The engine designations given are those of the New York Central nomenclature. Two particularly heavy locomotives, which are also among the newest, are H7A and NU-1A. Engine H7A has four driving axles, pilot and trailing axle, and weighs 332,000 lb. without tender; its heaviest axle-load is 65,000 lb. Engine NU-1A is a Mallet with two sets of drivers, each of four axles; it weighs 622,000 lb. with tender. This engine has a moment effect equivalent to about E62 over most of the range of the diagram.

MOMENTS AND SHEARS COMPUTED FOR TWO ENGINES COUPLED

It should be said that in all cases moments and shears were computed for two engines coupled, except in the case of M1 and NE-2A, which were taken single, followed by a train of 115,000-lb. capacity cars. The NU-1A was taken single followed by a train of 70-ton capacity cars.

Wrecking cars were plotted on similar diagrams, but they produce considerably lower moments and shears than do the heavy locomotives. The heaviest wreckers do not exceed in moment 800,000 ft.-lb. per rail on a 40-ft. span. Still higher effects are produced by a heavy engine (N1S) of the Pennsylvania Lines West, which operates over New York Central tracks in Cleveland territory. It produces moments and shears exceeding those due to E70 loading. The engine is of the 2-10-2 type, has a length between couplers (tender included) of about 90 ft., and weighs 651,000 lb. with tender. Its driving wheel-loads range up to 39,000 pounds.



MOMENT AND SHEAR CURVES FOR ENGINES IN USE ON NEW YORK CENTRAL LINES WEST OF BUFFALO, AND FOR COOPER LOADINGS

Group numbers represent the classification of engines for purposes of defined bridge capacity

The moments M and shears S produced by this engine on various spans (compared with those due to E70 loading) are, per rail: On 40-ft. span, $M = 1230$ (1147), $S = 135$ (132); on 60-ft. span, $M = 2330$ (2274), $S = 169.3$ (171); on 80-ft. span, $M = 3600$ (3781), $S = 200$ (217).

Exceeding all the engines, a special car of the Bethlehem Steel Co., built for handling heavy castings, produces the critical stresses. This car has 60,000-lb. axle-loads, and its moment and shear effects are considerably above E70 on short spans. On a 100-ft. span the car produces a single-rail moment of 5126, while E70 produces a moment of 5635.

With this graphical comparison in mind, it is evident that no one can yet say what is to be taken as the heaviest railway loading. The fact that the upper lines in the diagrams represent engines added only in the past three or four years is an indication of the fact that the growth of loadings is still in progress.

Heavy motive power affects only the road on which it operates, of course. Freight cars, however, circulate everywhere, and it is difficult to exclude them from any particular division. This is especially true of coal cars, since coal must be carried to every station and to all railroad terminals.

It is found that 140,000-lb. coal cars, which are in use on the Pennsylvania and the Chesapeake & Ohio lines, are equivalent to about E45 for spans up to 40 ft., tapering to E36 for 100-ft. spans. Such rolling stock, then, would fix the minimum loading for which bridges anywhere in the country should be designed, no matter how light the power used on a particular road. From the diagram it can be seen that some of our light engines are below E30 in their effect. If a road used engines of this kind, however, and designed its bridges accordingly, the structures would be overloaded if a train that was composed of heavy coal cars were run over them.

The 140,000-lb. car is 43 ft. 8 in. long, 31 ft. 10 in. between the truck centers, and 5 ft. 10 in. in truck wheelbase. Its dead weight is 50,800 lb., and when loaded with a 10% overload (or 154,000 lb.) its wheel loads are 25,600 lb. On a 100-ft. span such cars would produce a moment of 2995 per rail, as against 2817 for E36 loading.

Edge Taping Strengthens Fiber-Board Boxes

Tests of fiber-board boxes in the box-testing machine of the Forest Products Laboratory, Madison, Wis., showed that failure usually started in the scores at the edges. When adhesive paper or tape strips were applied over the edges the strength of the box was increased about 25 per cent.

SOCIETY SERVICE

A Section Dealing with the Results of Teamwork by Technical Men

St. Louis Electrical Engineers Advise Development Committee

In order that the representative of the St. Louis Section of the American Institute of Electrical Engineers on the national development committee might have back of him, in tangible form, the local opinion which he represents, resolution were adopted pertaining to the relation of the institute to its members, to other engineering organizations and to the public. Briefly, they are as follows:

That annual visits be paid to sections by national officers; that institute meetings to be held bimonthly in the various sections' cities, on schedule; that expenses of board members be paid; that the country be districted and a vice-president elected from each district; that the *Proceedings* be changed to 9 x 12-in. size, contain articles of live interest, current topics as well as technical articles, editorial reviews, abstracts only of strictly technical articles, and advertising; that a National Engineering Congress be held biennially for the discussion of all matters pertaining to the general profession of engineering; that the section views with disfavor any thought of losing the identity of the institute through substitution of a common engineering body, but does favor affiliations along present lines through the United Engineering Society; that the Associated Engineering Societies of St. Louis is a model of successful federation; that members of the local joint council be automatically members of a National Engineering Council; that participation in all public affairs by the local federation or the national federation shall first be approved by the respective councils.

Iowa Publicity Committee at Work

An intensive publicity organization is being perfected in Iowa by the Iowa Engineering Society. Minutes of a recent meeting of a committee in charge of the work indicate a plan by which the state is divided into 11 districts, with a subcommitteeman in charge of each district and having under him local representatives.

On district organization the following rules were adopted: That members or nonmembers may be chosen as district committeemen or local representatives; that the main purpose of the work is to obtain publicity for the profession, its work and its relation to the public, and not publicity for the society; that individuals should be chosen who are or can become acquainted with the editors of the most influential papers. District committeemen are to enlist the services of local representatives to organize and supervise the publicity work in their respective districts; to furnish to the central office lists of representatives and newspapers and to report to the central office, sending clippings of articles published.

On the local representatives depends the success of the plan. They are to make the acquaintance of the editors; to prepare news stories of engineering of local interest, to procure news items of general interest for distribution through the central office, as well as obtain publication of similar items sent to them.

In a report on the functions and work of the committee, salient features that were brought out were as follows:

The fundamental principle in publicity work is that the engineer is a public servant and must render nontechnical as well as technical service. For the former the engineer is urged to ally himself with local nontechnical organizations. He should offer his ability as an organizer and specialist in materializing ideas promoted by such organizations. In the technical-service publicity the effort should be made to prove that the engineer is a financial asset to his community. Newspaper work should be supplemented by personal talks to individuals and by addresses. General instructions call for the maintenance of so high an ethical standard that the engineer will not indulge in or seek to obtain personal publicity at the expense of some other individual.

LETTERS TO THE EDITOR

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Training in Latin and Greek Not Best for Engineers

Sir—Many years of study of the general subject of Latin and Greek as preparation for engineering, which subject is treated by Dr. M. E. Cooley as quoted in *Engineering News-Record* of May 8, 1919, p. 930, lead me to a conclusion quite opposed to the position taken by him. I am, therefore, led to offer the following principal reasons for my disagreement and my belief that these dead languages, if taught at all, should be incorporated into our teaching of English.

It is remarkable that this old controversy does not seem to down. On one side are men, some familiar with the ancient languages, who trace to them many advantages they have had from such knowledge, but ignoring the multitude of fellow students who, notwithstanding that acquirement, were never able to rise above mediocrity. On the other side are men who never studied Latin or Greek but, notwithstanding, have reached eminent positions in the world.

When a boy I studied Latin for four years and Greek for three. My study included some conversational "live" dialogues. All of this, I presume, fully meets Dean Cooley's prescription. Thus qualified, I shall try to be unbiased.

As all men differ in their capacities and opportunities, they should not and do not receive the same kind or extent of education. But, as of first importance, everyone of us should know as well as possible the language of his own country. Therefore, no education can be more valuable to an American "engineer trained for responsible citizenship" than to get a thorough knowledge of the use of the English language.

The study of the classics can have no influence whatever toward a better understanding of abstract sciences, such as logic and mathematics, or any of the concrete sciences, such as physics, chemistry, geology, astronomy, or

of the sciences of organisms, including their lives, from botany up to psychology, and even sociology. In fact, also the history of ancient civilization and of its stages of development can hardly be grasped by us in Greek or Latin as well as it can be in English when presented by specially trained linguists. The ancients at best had but rudimentary knowledge of all sciences and even less of the scientific method, which is gradually unravelling our most complex problems of practical life and our knowledge of all the fundamental inductions concerning our loftiest conceptions of religion, art and social life.

Greek and Latin of two thousand years ago do not and cannot give us, in any of these directions, what modern scientific knowledge and practical experience have given already and will surely continue to give; but they can give us something else. They can and do help us to understand and use the English language more accurately than by a knowledge merely of its words learned in childhood.

When I first gained this opinion, I asked myself, How then should I study Greek and Latin? As I had studied them? No. As my children studied them? decidedly, no. How, then, should they be taught?

Most thoroughly to understand and use a language, one should know, besides the meaning, also the derivation and life of its words, the way to form its sentences, and the relation of words and sentences to express our feelings, thoughts and conceptions. The English language was once Anglo-Saxon and into it were transfused later more than half of its words from the Norman-French after the conquest, and finally, for advanced knowledge, words from the Latin and Greek.

Therefore, we should be informed by our teachers, as in an interesting story, how the words of the English language were developed from crude origins, how they were influenced by internal and external causes, how and why they were changed from one period to another and gradually arrived where they are today—in short, we should learn the story of the life and growth of our language.

Such a story would raise a lasting interest in the growing young mind. As a first reading book, the edition of "Robinson Crusoe" written in monosyllables, almost all of Anglo-Saxon origin, might be an entertaining help. The history of the peoples who spoke these four languages—Anglo-Saxon, Norman-French, Latin and Greek—should then be learned, in order that the student may understand how and why their words and expressions were finally united with and converted into modern English.

For instance, under which conditions did our language ancestors derive their words, and which conditions caused the gradual changes in the words? What were their grammatical forms, compared with one another? Why and how did the Anglo-Saxon forefathers take over so many of its words and forms of sentences from the French language? And, finally, how were new words created to express the multiplying new ideas and conceptions, by utilizing Greek and Latin roots? Spencer says, "the development of language is a psychological process determined by social conditions."

Pari passu with these interesting stories to be told by the teacher, the young folks should memorize actual words of those old languages, with their original meanings and as used in conversational phrases, selected to cover those words that were gradually embodied in modern English. The words learned should not be vocabularies having no reference to modern English. Let us learn, for instance, the origin of the words "home," "love," "children," etc. Let us know when we see the word "geography" that it is made up of two Greek words, "*ge*," earth and "*grapho*," to write. Let us learn the declensions and conjugations in order to form simple sentences and phrases in those old tongues and so as to give the words life and interest in relation to our new tongue.

If Greek and Latin and also Norman-French and Anglo-Saxon were studied in this manner—and I see no reason why they could not be—we should better understand the spirit and weight of our words and sentences. Incidentally, we should automatically not be tempted to write the word "seperate" instead of "separate," nor say "this data" and "this phenomena" instead of "these data" and "these phenomena." Nor should we mistake the nominative for the accusative case, as is so often done, nor make any other misuses which together mean "bad" English. Our dictionaries have a list of phrases and expressions, mostly in Latin, which are used by us daily. Let us learn them early, with their original meanings, so that they are understood and correctly used—generally to differentiate or specialize the meanings when the phrases or expressions are interpolated in an English sentence.

It has seemed to me that if the study of these ancient languages were taught not as a "fad," which is evidently the case at present, but for real, practical, intellectual usefulness, we should read and hear a better language today than we do. All this interest and benefit could be obtained from efficient teachers trained along philological lines, in a fraction of the time now spent. One or two semesters at the utmost should suffice amply for teaching each one of our parent languages for the above purpose, including the interesting histories of their developments.

Why should we weaken our modern education by antiquated methods, surviving from the Middle Ages, when Greek and Latin were the only languages of culture and the only means of preserving the records of civilization and intercourse between the intellectuals of different nations? A thousand years ago the preservation of these languages was necessary, because without any printed books for general distribution there was a gradual breaking up—a vulgarization, for instance—of Latin into Italian, French, Spanish, Portuguese and Rumanian.

In our present age, however, with the constantly growing mass of necessary and useful knowledge which is pushing civilization ahead, it is becoming absolutely necessary to economize in our studies and in the time which can be devoted to them. The study of the ancient languages as above outlined would seem to be ample, if indeed such knowledge is at all necessary for most of the intellectuals of modern times. John Bright, Herbert Spencer and others who wrote excellent English say that their knowledge of Greek and Latin was not worth mentioning. The "humanists" of the Middle Ages should be transformed into "humans" of today. Waste, through conservation, should be converted into economy; extravagance, through limitation, into frugality.

One of the pet reasons given for studying Greek and Latin is to get "mental discipline." Faraday says that

"science is greatly superior to language as a means of discipline," and that it "culivates our judgment more safely and intensely." The best discipline arises when we act under laws and rules *without* exceptions, as in any scientific pursuit. The ancient languages have many exceptions to their rules, concerning genders, declensions, conjugations, etc., and even their sentences, as I remember, are not always as logical as algebraic expressions must be always.

Another of the pet reasons for holding on to Greek and Latin in the schools is that we may read the "classic literature of the ancients," which has been held as a model for civilization for several thousand years. How many Greek and Latin students of the present century are able to read, understand and really enjoy that literature in the tongues in which it was originally written, even if their minds could take themselves back into the actual state of civilization then existing?

Those who live today and must look upon the ancients as historical relics—magnificient and interesting in a museum, if you please—can certainly acquire more benefit and enjoyment by reading that same literature in the best translations, into English, French and German, of every ancient writer worth considering. Neither Americans nor Western Europeans need learn Greek and Latin for that purpose.

Finally, with reference to the editorial remark that colleges of literature and arts turn out men of more breadth and culture than engineering colleges: This may unfortunately still be true, but the reason, so far as my experience has gone, is not the study of Greek and Latin. There is another cause. The universities formerly had a rank much higher than that of the technical schools. Fifty years ago I heard it said, somewhat to my disgust, "Oh, he is not able or bright enough to study law or medicine; he must take up some engineering occupation or trade." Families of higher culture are apt to produce boys and girls of greater mental capacity and breadth. Their sons, therefore, as a rule were sent to the universities, and those who could not stand the greater strain selected engineering. This feeling was particularly common in England and Germany. It was not so in France, where engineers came often from the best families and socially had a higher standing than in any other country. M. Freycinet, for many years head of the French cabinet, was an engineer.

Greek and Latin have been studied within the past century mostly by those expecting to follow the legal and medical professions, rarely by engineering students. The lack of knowledge, until recently, concerning the origin and course of diseases was such that 39 years ago no less a person than Dr. Pettenkofer said to me: "In but few cases can we do more than make the best guess that our experience justifies." Since the advent of bacteriology, and progress along other lines, the medical profession has moved ahead with leaps and bounds, so that within a third of a century both death and sick rates in the most highly civilized countries have dropped in a great ratio than during many centuries before. Neither Greek nor Latin helped in this advance.

Since the Middle Ages even the greatest of the creating artists in music, painting, sculpture and architecture were not specially versed, if at all, in these ancient languages.

The engineering and allied professions, the students of which generally have not been obliged to study Greek and Latin, have contributed more to advance modern civilization than any of the above professions. By studying and utilizing the laws of nature, they have made it possible to travel over land and sea without limit and open up the possibilities of the entire earth for the benefit of men. They have introduced more rapid means of mental communication through the telegraph and telephone, without which the amount of our progressive work of today would be very greatly diminished. The achievements of mining, manufacturing, sanitation and agriculture during the past century did more to advance the human race toward higher planes than was done in any previous equal period.

I heartily agree with your correspondent in the issue of May 22, 1919, p. 1031, in his reference to Herbert Spencer, whose essay on "What Knowledge Is of Most Worth," written about 60 years ago, pretty thoroughly settles the question as to the relative value of the "classics" and of modern sciences. As Spencer in his early life had been an engineer himself, Dean Cooley should take that philosopher's opinion as applying especially to engineering students, and "as a means of training (them) for responsible citizenship."

New York City. RUDOLPH HERING, Consulting Engineer.

The Manning Formula Again

Sir—Considering the discussions that have recently appeared in *Engineering News-Record* [see *Engineering News-Record* of Jan. 16, 1919, p. 149; Mar. 13, 1919, p. 536, and Apr. 3, 1919, p. 685] regarding the treatment of the Manning formulas in the Miami Conservancy District's Technical Report, Part IV, it seems pertinent to add a few remarks concerning these equations.

Up to the time Professor King's "Handbook of Hydraulics" was published, which was after the manuscript for Part IV had gone to the printer, the equation generally known as the Manning formula had been mentioned but briefly in American engineering literature. For this reason, although it was known that the formula is used to a limited extent in certain foreign countries, it was not considered necessary to publish a detailed treatment of the equation, especially as our investigations had led to the conclusion that nothing could be gained by its use.

The formula recommended by Manning, given on p. 221 of Part IV, never found any appreciable acceptance among practicing engineers, although it is, next to the Ganguillet and Kutter formula, the best one so far proposed. It was this equation that was referred to on p. 243 of Part IV in the statement: "The average error of the results calculated by the Manning formula for the gagings of Humphreys and Abbot was 19.8%, while the average of those calculated by Kutter's formula for the same gagings was only 4%." These average errors were determined by Manning in a manner similar to that used by Leach in calculating the "average departure from mean" (*Engineering News-Record* of Mar. 13, 1919, p. 536) and consequently would not be affected by constant errors in velocity measurements.

The equation now known as the Manning formula is merely an exponential formula in which the coefficient is given as a function of n. It would have been discussed under the heading "Exponential Formulas," in Part IV, if it had not been for its connection with the

* Average variation from mean in per cent. of mean value.

original Manning equation which is not of the exponential type. Manning investigated this equation, in a slightly different form, and rejected it because it did not give satisfactory results for the Mississippi River gagings. Bazin, in his paper in "Annales des Ponts et Chaussées," 1871, entitled "Étude Comparative des Formules Nouvellement Proposées Pour Calculer le Débit des Canaux Déconverts," showed that an exponential formula is not the proper kind of an equation to represent the conditions of flow in open channels. He showed that the curve is not the right kind of a curve, that while it may be made to fit a small range in conditions in a given case, by varying the coefficients and exponents, it cannot be used as a general formula.

One way in which the Manning formula may be compared with Kutter's is to calculate, by the two equations, the values of n for several series of measurements, in channels where *the roughness conditions are constant* and then to compare the constancy of the calculated values. This method was used in several instances in Part IV. The method used by Leach in his studies, referred to above, was similar, except that he assumed that the roughness factor for a given channel should be the same for all stages, irrespective of actual differences in roughness conditions. Mr. Horton, in his reply to Mr. Leach, has already called attention to the great differences in actual roughness that may exist in a given channel with different stages. The Tadmor measurements, which Mr. Leach used and to which he gave greater weight than to any of the others which he investigated, may be cited as an example of such conditions. The experiment, made during the 2-ft. stage of September, 1916, which causes the Manning formula to appear so much better than the Kutter formula, was made when the water was comparatively low. For such stages the channel is smoother than it is during flood stages, when the other measurements were made. The bed and banks are more regular, and the disturbing effect of the fringes of trees along the banks, which is very marked during flood stages, is entirely absent. While this was not emphasized in our report, it was mentioned in the descriptions of the Tadmor measurements and also on p. 142. For the above reasons this experiment was omitted from the Tadmor series in the studies given on pp. 239, 243 and 260 of our report, and also in the study of the Manning and Kutter formulas given in the accompanying table.

The table printed above gives, for each of several series of measurements, the average value of Kutter's n, the average value of Manning's n, the difference in the two values expressed as a percentage of Kutter's n, the average variation in Kutter's n in per cent. of the mean value, the average variation in Manning's n, and the number of measurements in each series. It also shows the mean values of the average variations of the two factors and of the actual differences in the factors for the entire group of 241 measurements. The data chosen for this study include those used in comparing the Bazin and Kutter formulas, on p. 260 of our report, and also such data given in Table 112 of Professor King's "Handbook of Hydraulics" as might properly be used for this purpose. Owing to the fact that the calculations were made at different times, some of the values of average variation of Kutter's n are computed to tenths of a per cent. only, instead of to hundredths as are the others. However, this has no material effect on the results.

A study of the results given in this table shows some interesting conditions. A comparison of the last two columns shows that the average variation of the Kutter roughness factor is the greater in 12 cases and the less in 23. The mean variation of Kutter's n for all measurements is 3.58%, while the mean variation of Mannings' n is 5.02%, or about 40% greater. The difference between the absolute average values of the two coefficients varies from 0.8 to 43.5%, the mean value for the 35 locations being 10.1%. If the experiments made on the Bogue Phalia, the Mississippi, the Irawadi, and the Volga are omitted (the only ones made in channels of unusually large size) the mean variation of Kutter's n is 2.67%, the mean variation of Manning's n is 3.41%, and the mean difference between the two roughness factors is 5.18 per cent.

This shows that Kutter's formula is better for channels of ordinary dimensions as well as for channels of unusual size. In view of the large number of diagrams and tables that are available for aid in using the Kutter formula, the advantage of simplicity possessed by the Manning formula does not seem to be of great importance, certainly not of sufficient im-

portance to warrant its general adoption and the rejection of the Kutter formula. While the Manning formula might be used in approximate calculations, as might also several other equations, it would seem to be better to use the Kutter formula in all important calculations in channels of ordinary dimensions as well as in channels of unusual size. Although the Kutter formula is not ideal, it is the best we have at the present time.

IVAN E. HOUK.

Miami Conservancy District, Dayton, Ohio.

United States Chamber of Scientists Proposed for Engineers

Sir—I have read with much interest W. L. Saunders' article in your issue of Apr. 17, 1919, p. 756, on an Engineering Civic Federation. It appears to me to be the most practical and logical solution of the many troubles that beset the engineering profession at this time, but I would go farther.

Everyone is doubtless familiar with the activities and influence of the United States Chamber of Commerce in the commercial world. The federation proposed by Mr. Saunders would have a similar influence and effect on engineering and all scientific progress and civic betterment if open to all technical, scientific and engineering societies, to all technical engineers, surveyors, architects, and, in general, to scientific men or women who work with their brains more than with their hands in engineering and science in all branches.

Mr. Saunders has well said that engineering societies are not effective in public matters. The public and legislators cannot be made to believe that their aims are unselfish, although these classes are the most altruistic of the human race. One does not have to go far to discover the reason for this. Scientific men and engineers are all technical and the public and legislators do not want technics, but policy and (we trust) public betterment.

I remember very well when this fact was first brought home to me in the late '80s when the late E. L. Corthell, Lyman E. Cooley and several others, including myself, then secretary and director of the Southern Society of Civil Engineers, prepared a bill for the establishment of a Department of Public Works to take over the river and harbor work of the national Government and place it in the hands of the civil engineers. The bill was promptly killed as "class legislation."

The engineers in this country are, however, very restless, and something must be done to better their condition, which is certainly deplorable when compared with that of the workmen under them. This condition has been brought about largely by the action of the War Department in this war in establishing the rank of "engineer" from men more noted for their brawn and fighting ability than for their engineering knowledge, in many cases. Pick-and-shovel men, railroad trackmen and trainmen, chauffeurs and auto-repair men and even lumberjacks were all called "engineers," and the general public does not discriminate.

These conditions must be radically changed, and the American Association of Engineers and Engineering Council are doing a praiseworthy work, but they cannot reach the great mass of the people, and so wield an overpowering influence as can a chamber of science, with a membership of half a million.

Important as the salary question is, it is not everything, and the result can perhaps be brought about in a more dignified and desirable manner. My old professor urged his students to give no thought to pecuniary emoluments but to rest assured that with professional success "all these things would be added."

I do not like the word "federation." It savors too much of a labor union. I prefer United States Chamber of Scientists. If the public knows that half a million voters are behind us we carry far more prestige than 50,000 could possibly do, and if a measure is before Congress it may be embodied in a bill that will not appear selfish, sordid or as class legislation, but, as the Chinese told his partner, who objected to certain items not being specified in a bill they were about to present, "You no see 'em, but they there allee same."

And now comes the report that the Boston engineers have joined the American Federation of Labor, a trade union. Shades of the immortal Stevenson, Roebling, Eads and Francis! And this is the modern Athens, city of culture and of the Pilgrims, and my birthplace!

Everyone should read the admirable article by Mr. Saunders and also the able address of W. W. K. Sparrow, chief engineer of the Chicago, Milwaukee & St. Paul R.R. printed in the April number of the *Monad*, the organ of the American Association of Engineers, both of which advocate a chamber of commerce of engineers along similar lines. No better man can be found for president than Maj. Gen. George W. Goethals, as proposed by Mr. Saunders. I have had the pleasure of knowing him for nearly 30 years. One of the first activities for this chamber of scientists to undertake will be educational and missionary work among the people, and especially among the engineers of Boston.

J. FRANCIS LE BARON,
Panama City, Fla. Consulting Engineer.

Variation of Roughness Coefficient in Manning's and Kutter's Formulas

Sir—Concerning the correspondence in your issue of Jan. 20 and Mar. 13 under above heading, and also Mr. Houk's most interesting report on the "Calculation of Flow in Open Channels," I trust the following statement will not be regarded as controversial:

I notice that all of the engineers concerned use the gagings of the Irawadi at Saiktha as an example. I have a very high respect for those investigations, but I think, considering their date and the methods used, that it is unwise to regard them as sufficiently authoritative for testing the newer standard formulas. The exigencies of the war have separated us from libraries, so I speak from memory, but I believe that (1) these experiments were made before 1880; (2) the standard apparatus was the twin float, though current meters of an experimental type were also employed; (3) the results when plotted against any of the newer standard formulas, Bazin's (1899) or Manning's, are less concordant than the average of modern observations.

For their date the Irawadi experiments were first-class, but I think that in the present state of knowledge they, like the earlier Mississippi work, should be considered as second-class only.

I would add that for the present purpose, their selection, even if they were first-class, appears unfortunate. The investigation is concerned with changes in Kutter's (or Manning's) n and Bazin's γ produced by variations in gage heights. The Saiktha gage site is situated up-

stream from a bar and crosses a deep pool. Thus, the conditions affecting the connection between the gage height and the discharge must be abnormal when compared with those existing in the ordinary cases to which it is desired to apply the results of the investigations.

Kuala Lumpur. P. PARKER.

Definition of Engineering

Sir—Writing definitions of human vocations is not a simple matter, as Mr. Condron has doubtless found out, judging from your issue of May 29, 1919, p. 1079.

Attempting to make a suggestion, a definition of engineering was formulated, containing 72 words. By revision, it was reduced to the form which follows, containing 45 words. This is thought to be sufficiently inclusive and not too inclusive. It is not the result of the effort of one mind, but rather of the efforts of three minds.

For use in license laws it seems to be desirable to define not only engineering but professional engineering, or perhaps a professional engineer. Therefore, a definition of professional engineer is added:

> Engineering is the intelligent application of the laws of mathematics and physics and often those of other sciences in the design, construction and operation of machines and the physical structures of public and private enterprises, and in the discussion, investigation and solution of related problems.
>
> A professional engineer is one whose vocation is engineering.

APPLIED SCIENCE.

Classes Draftsmen With Engineers

Sir—In your issue of Apr. 24, 1919, p. 834, Thomas P. Morrissey makes a statement to the effect that draftsmen are to be classed in the same category as bricklayers, carpenters and other mechanics. He then asks these questions: "Are they engineers? Tell me, now, are men of this type qualified to receive as much or more than mechanics? What do you mean when you say 'engineer'?"

Of a similar tenor are the remarks of Palmer C. Ricketts in your issue of May 29, 1919, p. 1075 where he says, "The difficulty is that common surveying and ordinary drafting are not difficult to learn and the law of supply and demand takes care of the pay for this kind of work. It is also a fact that a good carpenter is often worth more to a community than a good leveler or a good draftsman."

Now, giving the matter honest and due consideration, is it really fair, just, or even correct to give the young graduate engineer who is serving as a structural draftsman a classification on a par with, or even lower than a mechanic? Take my own case, which is fairly typical. During the summers of 1913, 1914 and 1915 I earned a part of the expense of technical training by working at the carpenter's trade, and I am capable of holding the best kind of a carpenter's job today. From this experience I can say that any lively young man with a whit of mechanical ability can learn the carpenter's trade in six months.

Engineering knowledge is not gained with any such ease. If, then, the difficulties in becoming proficient as a competent structural draftsman are to have anything to do with his worth as compared with that of the carpenter, the odds are heavy in favor of the structural draftsman. Moreover, the draftsman in preparing his drawing lays out the work and directs the activities of mechanics. Is it not usually considered in the industrial world that the man who directs the activities of others is to be given compensation and rank above them?

On the other hand, how many mechanics can be found who are competent to prepare a rational and economical design in structural steel or reinforced concrete? It may not be the constant duty of the structural draftsman to perform such work, yet it is required of him at times, and he is expected to be able to do it at any time. To suggest that a carpenter or mechanic could do it, or attempt it, is positively absurd.

It is true that complaint regarding the classification and pay for engineering services has come largely from draftsmen and instrumentmen. And the reason is this: Compensation for a mechanic's services in 1914 was less than for the draftsman. Since that time the increase in pay of the former has kept pace with the increased cost of living because of his union and the urgency of war work. The draftsman's pay, however, has not kept pace with the increased cost of living and today he is paid no more than the mechanic and, in some cases, less.

Our Government has compiled figures to show that the increase in cost of living has been 66% since 1914. Draftsmen's salaries have increased a spare 25 to 30%. Mechanics' wages have increased the full 66% and in some cases have doubled.

Now, as to "What is an engineer?" and "Is a structural draftsman an engineer?" I should say that an engineer is a man who has, by endowment and development, what I would call the engineering mind. The engineering mind works in two phases, the analytic and synthetic, to direct the forces of nature toward the upbuilding of modern industry, and for the benefit of mankind.

In order so to direct the forces of nature, the engineer must conceive a structure, a machine, a railroad, a plant, or perhaps a whole industry. Such a conception takes place in the mind of the engineer and must be presented to the minds of other engineers and workmen before it can become a reality. This presentation is usually made through the medium of an engineer's drawing. Here is the function of the engineering draftsman.

Usually the engineer does not make his own drawing but details this work to another engineer—a draftsman, usually younger, of less experience and naturally subordinate to his instructions. I have called a draftsman an engineer because he must have, to a certain degree, the same engineering mentality or mind as has his superior, else he will not efficiently and successfully grasp the conception which his superior holds in mind, and place it for him into an intelligible drawing. I would say, then, that a draftsman, if competent, is a minor or junior engineer, but an engineer, nevertheless.

I am not alone in this opinion. For example, in "Design of Plate Girders" by Lewis E. Moore, associate professor of structural engineering at the Massachusetts Institute of Technology, occurs the following: "The draftsman who plans his work with reference to needs of the shop and erection department, while carry-

ing out the intention of the designing engineer, is entitled to a part of the credit for the completed work and may rightfully feel that he is an engineer, not a mere mechanic." A. F. FOWLER.

Detroit, Mich.

Chart for Estimating Motor Truck and Trailer Haulage Costs

Sir—The writer has read with interest several articles appearing in *Engineering News-Record* relative to the operating cost of a five-ton truck. I am sending you herewith a chart which was compiled originally for the purpose of comparing the operating cost of a five-ton truck and a five-ton truck with trailer. The chart is based on the assumption of a five-year life of the truck, averaging 300 days per year.

It is, of course, impossible to make any rule which will fit all the various conditions encountered in motor-

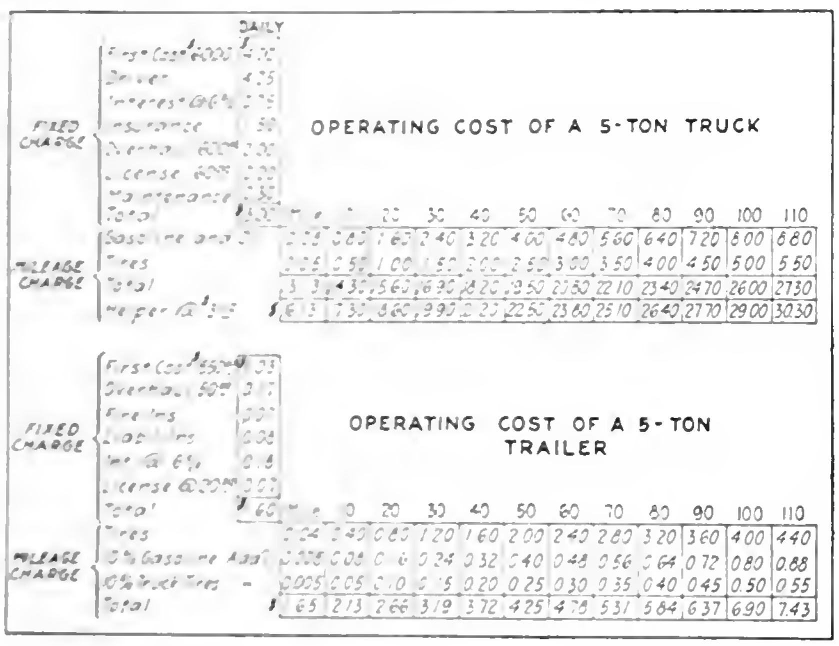

CHART FOR RAPID ESTIMATING OF TRUCK AND TRAILER COSTS

truck haulage, and it has therefore been my intention to derive figures which will fit the majority of cases. I have also tried to divide the operating costs into a fixed charge and a mileage charge, although really all of the charges listed as fixed are dependent upon mileage, with the exception of interest, insurance and license. Gasoline and oil are based on current prices, and the average mileage obtained per gallon. Tires are reduced to a cost per mile by dividing the list price by guaranteed mileage.

The operating cost of the trailer is estimated in exactly the same manner as the above. The average increase in gasoline consumption due to the trailer is 10%, and the increase in wear on truck tires is about the same.

The chart was reduced to mileage, in order to estimate rapidly on a known haul. For instance, a case comes up in which two five-ton trucks are engaged in a haul of say 25 miles, or 50 miles for the round trip. A glance at the chart shows a cost of $19.50 per day per truck, or $39.00 for the two.

If conditions are right, the trailer can be used displacing one truck. The cost is then $22.50 for the truck (with helper), and the trailer operation costs $4.25—a total of $26.75. If the resulting saving of $12.25 is credited to the trailer, it is not long in paying for itself.

The costs above may seem low, and unquestionably there are many items which might legitimately be added. The garage charges have been left out, as they vary. Against a large fleet, there may be charged superintendance. Board and lodging of a driver on the road may occur in a few instances. The purpose of the chart, however, is to strike a fair average.

A careful analysis of hauling costs is sometimes disconcerting to the truck operator, as not enough study has been given to this particular problem. Investigations should be made before and not after purchase, as changes invariably prove expensive. The trailer has a large field of usefulness, and only a careful study of hauling conditions is required to open it up.

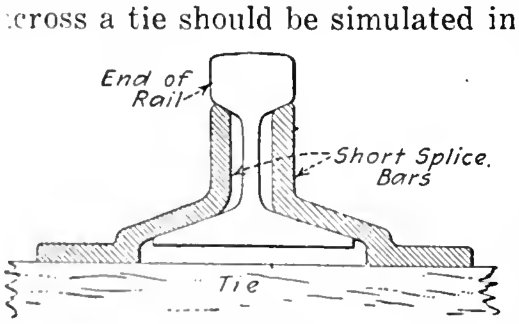
Rail Joint to Carry Rails by the Heads

Sir—After a long journey across the continent, listening to and observing the conditions and reactions of rail joints, a few possibly new thoughts on the subject are not inopportune. In view of multitudinous repetitions of wheel passes—each of minute effect—combining to produce evident effects on the rail, it has occurred to me that in order to receive uniform wear from the wheels a stretch of rails must be homogeneous through the junctions or joints.

Without any attempt to criticize present modes of connecting rails, and as a wholly novel contemplation of the problem, it is suggested that the posture of a rail across a tie should be simulated in connecting rails on a tie — that is, there should be present across the gap at rail ends—and for both rail ends in common—the combined head, web and base of a rail to carry the wheel through the juncture, identically as it is borne by a rail across a tie.



RAIL JOINT GIVES HEAD SUPPORT TO RAIL ENDS

Recent reports of the American Railway Engineering Association on tests of short four-hole angle bars indicate that two-hole angle bars of length equal to tie width, connecting rail ends on a tie, offer probably as much resistance as the rail itself. With the flanges of the splice bars extended laterally and depended below the base of the rail to form feet resting on the tie, the base of the rail would be held out of contact with the tie, and the heads of the two rail ends would be supported by a combined web and base in the same way as the head of a rail crossing a tie. The principle is shown by the accompanying section through the gap at the joint. The wheel drop incidental to the gap at rail ends is negligible, therefore actual continuation of the rail head through the gap is not essential. This method of joining rail ends might be termed a rail-joint chair, and it is the elementary form of many rail-joint inventions.

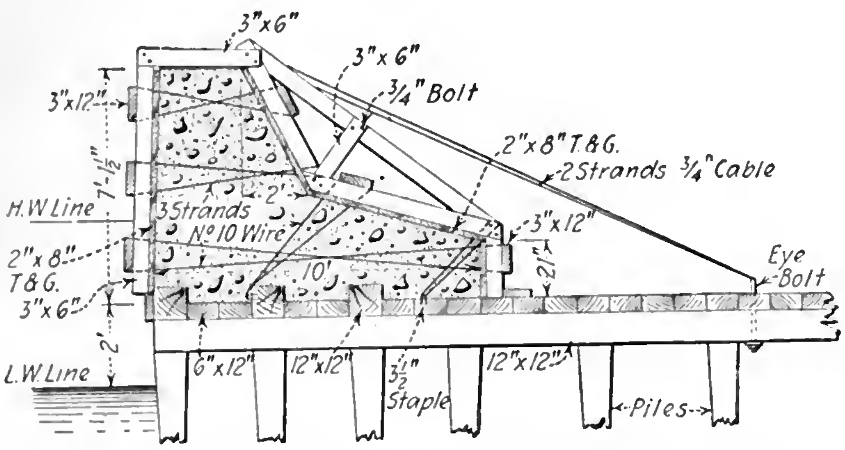
Los Angeles, Calif.

HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Unit Form Permits Building Concrete Wall on Pier Edge

CONCRETE bulkhead walls on the water side of piers present some difficulties in construction, on account of the necessity of having outboard bracing, and also because of the possible entrance of water into the forms with the rise of tide or water level. The form shown in the accompanying sketch was used by



FORM FOR CONCRETE WALL ON EDGE OF PIER

Henry Steers, Inc., of New York City, in the construction of a pier in Brooklyn and was devised to meet the difficulties.

Forms are built in panels 15 ft. long, are moved from place to place, and are used successfully several times over. Each panel consists of transverse frames, made up of 3 x 6-in. sticks spaced 5 ft. c. to c., with outside and inside lagging of 2 x 8-in. tongue-and-groove planks, the whole resting on the timber framing of the pier proper. The form is held against outward movement by the two strands of ¾-in. cable fastened to the upper bolt of the frame and to an I-bolt back on the pier. The form is wired together, as shown, against interior buckling, and held down to the pier proper by wires attached to staples in the deck.

The sections are quickly erected with the aid of a floating derrick. Concrete is started as the tide recedes below the level of the deck, and it has been found that the 2 x 8-in. tongue-and-groove boards offer sufficient protection to the concrete against scouring action of the rising tide.

The form was described in the "Contractors' Atlas" of June, 1919, by A. R. Moxter, superintendent of construction of Henry Steers, Incorporated.

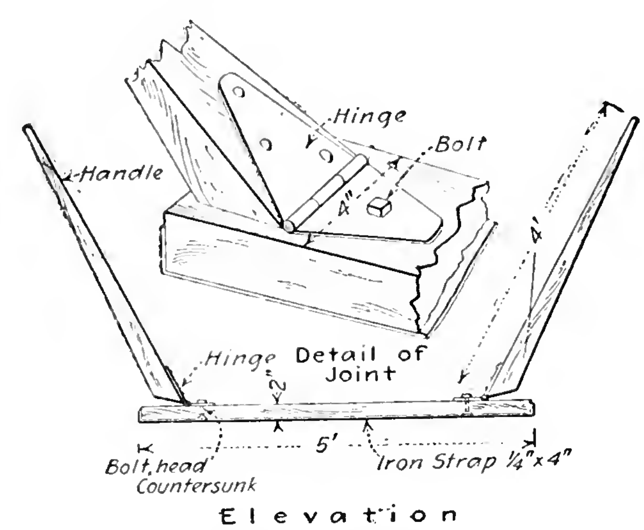
Short Straight-Edge With Handles for Use on Narrow Widths

By George W. McAlpin
Point Pleasant, W. Va.

A CONVENIENT, short straight-edge for leveling off concrete paving in narrow widths is shown herewith. With this tool it was found that two men could easily accomplish the work previously done by four, operating the old type without handles.

Other Articles in This Issue of Interest to Contractors:

It is made of a 2 x 4-in. scantling, laid flat, and is provided with an iron strap, ¼ in. thick, on the bottom. The handles are so attached by strap hinges and one bolt that they may be moved in two directions. This



DETAILS OF SHORT STRAIGHT-EDGE—NOTE DOUBLE HINGED JOINTS

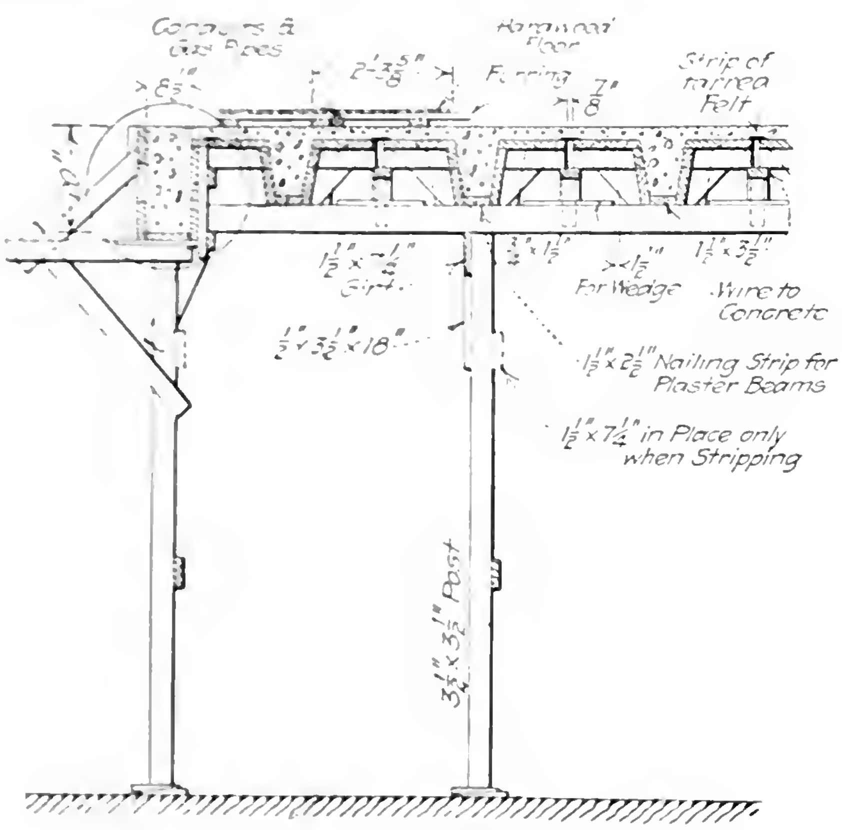
permits the operators to work from a standing position, instead of the kneeling position required for operating with efficiency the straight-edge of the ordinary type.

The double-hinged joint also permits the usual sawing motion that is employed in the cutting off of concrete surfaces.

STRAIGHT-EDGE WITH HANDLES IN OPERATION ON NARROW PAVEMENT

Forms for Concrete Floor Made Up of Wood Frame Sections

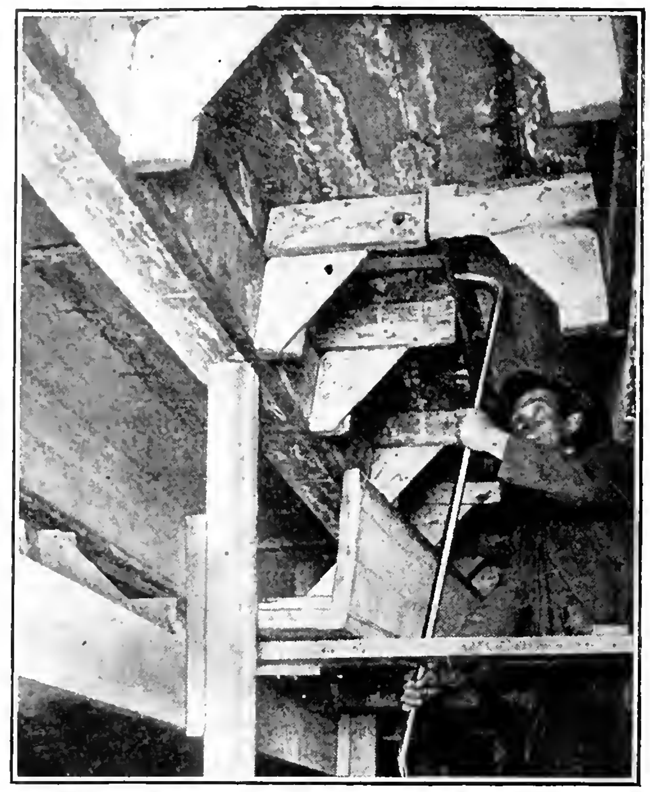
SECTIONAL wood forms, of inverted-trough section, were used over and over again in the construction of the floors of a reinforced-concrete apartment house at Salt Lake City, Utah, by Villadsen Brothers, Inc., contractors, of that city. Details of the construction and views in place are given in the illustrations printed herewith.



WOOD BOX FLOOR FORMS READY FOR USE
Note small end section where beam joins girder

The floor consists of a $2\frac{1}{2}$-in. slab supported on tapered beams, spaced 3 ft. c. to c. spanning between the girders on the columns. Forms for the beam and slab unit are in about 10-ft. lengths of an inverted "L" shape, making up one of the tapering sides of the beam and the bottom of half of the slab width between beams.

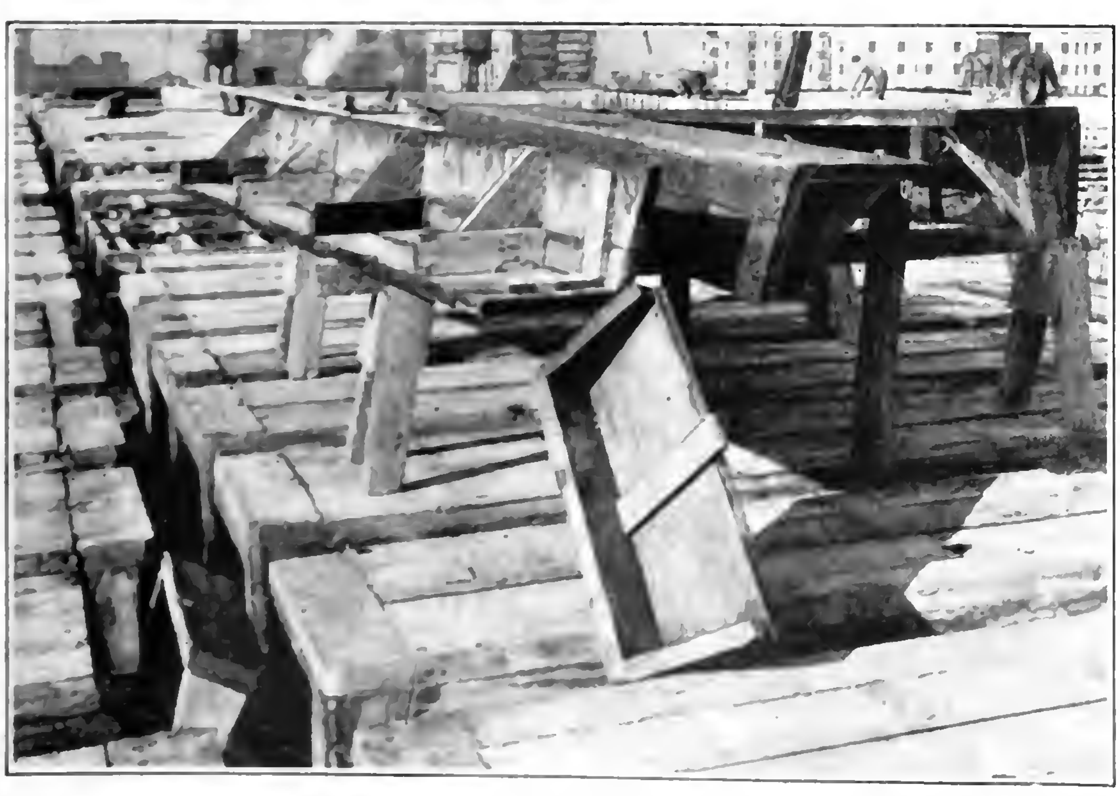
These units are carried on stringpieces and girts at the bottom of the beam section, and at the middle are supported on elevated $1\frac{1}{2}$ x 3-in. stringers which rest on small supports tacked to the stringpieces. A $\frac{7}{8}$-in. opening between adjacent slab forms is covered with a strip of tarred felt over which the concrete is poured.



SPECIAL BARS USED TO REMOVE FLOOR FORM UNITS
Note scaffold to catch forms

The bottom of the beam is carried on a separate strip, which is permitted to remain in place after the forms are removed, to serve as a tacking strip to which are attached the plaster ceiling boards. The ends of the floor-beam forms are beveled, and a separate piece squaring the ends is used to facilitate form removal.

In the stripping, wedges against a small piece on the stringpiece are knocked out, the vertical holding strips are removed, and the forms are taken off with bent bars, as shown in one of the views. Special scaffolding was provided about 2 ft. below the forms on which to drop them in the removal process. The forms were used many times without any considerable intermediate repair being required.



RE-USABLE WOODEN FLOOR BOXES FOR CONCRETE FLOOR

Washing Sand for Concrete

BRITISH practice in preparing fine aggregate for concrete was outlined by P. G. H. Boswell in a paper before the Concrete Institute, as follows: "Some method of 'scrubbing' is the only way to clean ballast effectively from adherent clay and loam. On the other hand, the dust produced in the crushing of aggregate can easily be washed away. If the aggregate is required down to 50-mesh, an upward current of water at ordinary temperatures of about 5 ft. per minute will remove all material smaller than this. If the aggregate is required to be not smaller than 20-mesh, a velocity of about 15 ft. per minute will remove the material not required."

Roumania Wants Americans to Rebuild Its Bridges

Commission Now in This Country to Make Arrangements for Delivery of 25,000 Tons of Bridge Steel

Opportunity is afforded American bridge contractors to enter the European field, in the construction of a number of large bridges destroyed in Roumania during the war. There is now at the Hotel Cumberland, New York City, the Roumanian Bridge Commission, sent here by the Roumanian government to get proposals on this bridge reconstruction. The total amount of steel needed is about 25,000 tons, practically all in railway single-track bridges, although some highway bridges are required.

While the Roumanian finances are in process of reconstruction, it is probable that the firms taking over the bridge work will have to arrange for a time at least to finance the projects, but the stability of Roumania seems assured, and the rapid assumption of its financial responsibilities a matter of a short time.

The principal bridge to be replaced is that over the Borcea branch of the Danube, on the line which connects Bucharest with the sea at the port of Constanta. This point of the Danube is divided into two branches, and there is a large bridge with cantilevers of about 400-ft. span in each branch. One of these branches was destroyed by the Roumanians in their retreat from the Dobrudja. The Germans, it is understood, had intended to replace this bridge, and have in their shops in Germany a new bridge of about 2700 tons, of which 2000 tons is ready to deliver. The Roumanians, however, do not choose to do business with the Germans and utilize this structure.

It is announced that spans from 20 to 65 m. are required, a total of about 1500 m. for double-track and highway and 1700 m. for single-track railway bridges. Delivery should be made as soon as possible to Roumanian ports, the principal one of which is Constanta on the Black Sea.

Army Equipment from France To Be Distributed to States

In response to a request from the Department of Agriculture, the War Department has ordered returned from France, as soon as possible, a large quantity of engineering equipment to be distributed by the Department of Agriculture through the Bureau of Public Roads to the states for use in the construction and maintenance of Federal-aid highways. The equipment will be apportioned on the basis of the allotments in the Federal-aid road act in the same way in which the 20,000 Army motor trucks are now being distributed.

Included in the equipment which has been requested are 1500 caterpillar tractors; 400 road rollers, and a large number of concrete mixers, road graders, elevating graders, rock crushers, industrial locomotives, industrial-railway tracks, dump cars, steam shovels, hoisting engines, electric motors, and quantities of smaller equipment. The Bureau of Public Roads will distribute this equipment, when received, on requests from the state departments.

Employment Bureaus

Engineering Societies' Employment Bureau of the four founder societies, conducted by Engineering Council Employment Service, for members and for other professional men introduced by members. Especial attention for those released from Government service. Address, 29 W. 39th St., New York City.

American Association of Engineers, 29 S. La Salle St., Chicago. Service to members only, but Army or Navy Engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

Engineers' Service Bureau, 57 Post St., San Francisco. Only applications by mail or wire will be considered.

Professional and Special Section, United States Employment Service, 469 Fifth Ave., New York City.

Reëmployment Committee of New York City for Soldiers, Sailors and Marines, 233 Broadway, New York City.

Extend Alaska Railway Location

The Alaskan Engineering Commission has sent out a party to locate the route of the Alaska Government railway on the 100-mile gap from the Susitna River north through Broad Pass, to connect the present line running north from Seward and Anchorage with that running south from Nenana. The party is in charge of T. W. Secrest. William C. Edes is chairman and chief engineer of the commission. The progress of work on this railway was described in *Engineering News-Record* of Jan. 2, 1919, p. 46.

Commerce Chamber Committee Railroad Report

Conclusions Provide for Early Return of Roads to Private Operation With Guaranteed Returns

Emphasizing adherence to a policy of corporate ownership and operation of railroads, the committee on railroads of the Chamber of Commerce of the United States, appointed to investigate and report on remedial legislation, has submitted 10 separate recommendations providing for the return of the railroads to corporate operation as soon as the necessary legislation can be enacted, the consolidation of a limited number of strong competing systems, exclusive Federal regulation of capital expenditures, and guarantee of return on investment through rate regulation. The recommendations of the committee are now being submitted to all members of the Chamber of Commerce in the form of a letter ballot, merely as a means of obtaining tthe opinion of the commercial organizations of the country regarding a final settlement of the railroad situation.

The recommendations of the committee provide for:

Adherence to the policy of corporate ownership and operation, with comprehensive regulation.

Return of roads to corporate operation as soon as remedial legislation can be enacted.

Adherence to the period of Federal control as now fixed unless and until impossibility of remedial legislation in this period clearly appears.

Permission for consolidation in the public interest, with prior approval by Government authority, in a limited number of strong competing systems.

A requirement that railroad companies engaging in interstate commerce become Federal corporations, with rights of taxation and police regulation reserved for states.

Exclusive Federal regulation of capital expenditures, and security issues of railroads engaged in interstate commerce, with provision for notice and hearing for state authorities.

Federal regulation of intrastate rates affecting interstate commerce.

A statutory rule providing that rates in each traffic section shall yield an adequate return on a fair value of the property as determined by public authority.

Payment into a fund of a share of the excess earned by any railroad system under application of the above statutory rule over an equitable minimum return upon the fair value of the property, this fund to be used as Congress directs for strengthening general railroad credit and increasing general railroad efficiency.

A Federal transportation board to promote development of a national system of rail,

water, and highway transportation and articulation of all transportation facilities.

In explanation of the recommendation for consolidating a limited number of strong competing systems, the committee points out that the regrouping should be about the present large systems and not by territorial subdivisions of the country, maintaining competition in service and permitting financial aid to weak roads from strong systems.

In connection with the provision guaranteeing return on investment through rate adjustment and the turning over to Congress, to strengthen railroad credit, of income in excess of an equitable return on investment, it is stated that the purpose is to prevent individual companies from obtaining excessive profits at the expense of others and that the proposed rule would not deprive the present prosperous roads of an equitable return, but would at the same time tend to strengthen railroad credit as a whole.

Transport Committee Plans Better Highway Transportation

With the idea of producing better transportation conditions and increasing the use of highway haulage throughout the country, the highways transport committee of the Council of National Defense has sent out two bulletins. One of these consists of a letter to all representatives and senators requesting that they have surveys made of their districts with a view to determining where there is a lack of transportation facilities and a need for rural motor express; the other concerns a nation-wide campaign for the adoption of uniform highway traffic regulations and gives notice of the preparation of directions to traffic. This, it is believed, will decrease the large number of accidents that now occur upon the highways.

In writing to the senators and representatives, attention is called to a number of examples where farm and other products have been ruined on account of inadequate transportation facilities. It is felt that conditions similar to the examples given exist, in all probability, throughout the country. The survey is for the purpose of giving the council the necessary information for establishing motor transportation for such localities. The communication sets forth that the railroads and electric roads which need more traffic will be benefited by the traffic developed and also that the cost of the commodities will be decreased by the increase in the supply.

The traffic regulations referred to are those recently compiled by William P. Eno and submitted for criticism to various traffic associations and highway engineers throughout the country. They give minute directions for the proper procedure in driving motor vehicles on the highways, and for pedestrians in crossing the highways. These have been printed in a folder for distribution. It is hoped by this means to reduce the number of accidents both in cities and country districts.

Arguments Against National Highways Answered

Highway Industries Association Replies to Criticisms of the Proposed System by Secretary Houston

Replying to arguments advanced by Secretary of Agriculture Houston, as reported in *Engineering News-Record* of May 29, 1919, p. 1083, against the proposal to form a Federal Highway Commission to build and maintain a national highway system, the Highway Industries Association calls attention to the impossibility of obtaining such a system by present methods. The fact that the proposed law would not interfere in any way with the coöperative plan now existing between the states and the Federal Government, as suggested by Mr. Houston, is also brought out. Extracts from the association's statement follow:

The National highway bill introduced into Congress by Senator Townsend, providing for the creation of a Federal highway commission and the establishment of a national system of highways, is a piece of legislation designed to bring about the construction of a national highway system in a reasonable length of time, to coördinate all the highway activities of the Federal Government, and to publish statistics and data on highway transportation, construction and maintenance for the benefit of all the people.

Arguments made against this bill in a letter from the Secretary of Agriculture to a city chamber of commerce were: "That the roads in each section of the country are of varying degrees of importance in the service rendered or that may be rendered to any particular locality. That the traffic conditions vary greatly in the different sections. That the state highway departments are better able to classify the roads than anyone else. That under the present Bankhead bill the Government is coöperating with state highway departments in the classification of the roads, and that when the classification has been carefully made, and by agreement between the state highway departments of adjoining states, the roads of first importance generally meet at state boundaries." Having the above points in mind, Mr. Houston stated that he could not see the wisdom of "substituting for the present coöperative program a plan which would commit or limit the Federal Government to the construction of two Federally-owned trunk-line highways in each state."

The national highway bill does not in any way interfere with the plan now existing among the states to coöperate with the Federal Government. It only substitutes for the Secretary of Agriculture the Federal Highway Commission, which, under the law, is charged with the duty of carrying out the provisions of the Federal-aid law as now operated, and all other obligations or contracts entered into by the Secretary of Agriculture with the respective states. The national highway bill is entirely a new piece of legislation. Its object is to build trunk-line highways in each state, to the extent of not less than 2% nor more than 5% of the total mileage of the state, and to join them up with the main trunk-lines of other states, so as to make a complete national system connecting the entire country. It creates a system of national highways, independent of the states—highways that will carry interstate traffic and that are necessary for the welfare of the country as a whole.

Under the present Federal-aid law the Federal Government has no power to select the roads in any one state that will be improved. The initiative is with the state highway departments, and in many instances is really with the counties, which have to put up the state's share of the money.

The only limitations prescribed by the Federal-aid law are that the roads shall be "rural post roads." When a road has met this condition, it is the duty of the Secretary of Agriculture to give his approval to its construction. All Federal-aid projects start with the 48 state highway departments and such projects are considered in 48 different lights, by 48 different men, holding 48 opinions, and it can be seen that a national plan that would evolve from such a procedure would be most chaotic, to say the least. Furthermore, the personnel of these departments, and with them the state highway systems, are constantly changing. It is also impossible under the Federal-aid law so to coördinate the 48 state systems that a plan would be finally evolved that would form a connected system throughout the country in a lifetime.

Many of the states have laid out a system of state highways. Many of the roads as laid out, on which Federal-aid is being expended, should not be and never will be classified as national highways, but they constitute a large portion of the mileage of the plans that have been approved as a general state system, and on which there has already been granted Federal aid.

We have seen the road work of the country expand from the township unit into the county unit; from the county unit into the state-aid unit; from the state-aid unit to the state unit; from the state unit to the Federal-aid unit, and it is but logical and reasonable that the final steps should be taken by establishing a Federal unit.

Many of the highway activities of the states were carried on in coöperation with the agricultural departments of the state or with the agricultural colleges, but it was soon found necessary to provide an independent unit of the state Government to look after this one important development. Likewise, the day has come when the road work of the Federal Government should be separated from the Agricultural Department. The advocates of good roads are only asking in this national highway bill that the roads should be put on an equal footing with the other departments of the Government, so that they can receive proper consideration and study.

Bids for Hetch Hetchy Dam Asked

Bids for the construction of the Hetch Hetchy dam for the San Francisco water-supply will be opened July 30. The dam will be of cyclopean concrete, 212 ft. high above the stream bed, but designed for a possible addition of 100 ft. The thickness will be 320 ft. at the lowest point, 168 ft. at the stream bed and 25 ft. at the 212-ft. height, where the length will be 600 ft. There will be 128,000 cu.yd. of excavation and 360,000 cu.yd. of concrete. The contract provides a bonus of $200 a day for completion in less than the 900-day contract period and a penalty of like amount for noncompletion. The estimated cost of the dam is $4,000,000. M. M. O'Shaughnessy is city engineer.

Public Service Engineers of New York Organize

The engineers of the Public Service Commission, New York City, have formed the Rapid Transit Engineers' Association. It is stated that these engineers have received no increases of pay in the past five years.

To discuss the problem, the foregoing association (whose membership is now about 600) has called a meeting to be held June 26 at the Municipal Building. To this meeting, engineers of other departments of the city Government than the Public Service Commission have also been invited to come.

Imperial Valley Active on All-American Canal

A contract was recently entered into between the United States and the Imperial Irrigation District, and it was ratified by a two-thirds majority of the voters within the district. Under this contract the district undertakes to construct an All-American canal from

Laguna Dam to serve the present irrigated area within the United States in Imperial Valley. It is contemplated that this canal will also serve all of the additional land, to the east, north and west of the present irrigated area, that can be irrigated from the new canal by gravity. A delegation representing the district has been sent to Washington to complete negotiations with the Government preparatory to beginning work.

Labor Advocates Scientific Research

A resolution in favor of a "broad program of scientific and technical research" was adopted by the American Federation of Labor at its Atlantic City convention, concluded this week. The supporting arguments, as well as the resolution itself, follow:

Whereas, scientific research and the technical application of results of research form a fundamental basis upon which the development of our industries, manufacturing, agriculture, mining, and others, must rest; and

Whereas, the productivity of industry is greatly increased by the technical application of the results of scientific research in physics, chemistry, biology and geology, in engineering and agriculture, and in the related sciences; and the health and well-being not only of the workers, but of the whole population as well, are dependent upon advances in medicine and sanitation; so that the value of scietific advancement to the welfare of the nation is many times greater than the cost of the necessary research; and

Whereas, the increased productivity of industry resulting from scientific research is a most potent factor in the ever-increasing struggle of the workers to raise their standards of living, and the importance of this factor must steadily increase, since there is a limit beyond which the average standard of living of the whole population cannot progress by the usual methods of readjustment, which limit can only be raised by research and the utilization of the results of research in industry; and

Whereas, there are numerous important and pressing problems of administration and regulation now faced by Federal, state, and local Governments, the wise solution of which depends upon scientific and technical research; and

Whereas, the war has brought home to all the nations engaged in it the overwhelming importance of science and technology to national welfare, whether in war or in peace, and not only is private initiative attempting to organize far-reaching research in these fields on a national scale, but in several countries Governmental participation and support of such undertakings are already active; therefore be it

Resolved, by the American Federation of Labor in convention assembled, that a broad program of scientific and technical research is of major importance to the national welfare and should be fostered in every way by the Federal Government, and that the activities of the Government itself in such research should be adequately and generously supported in order that the work may be greatly strengthened and extended; and the secretary of the federation is instructed to transmit copies of this resolution to the President of the United States, to the President pro tempore of the Senate, and to the Speaker of the House of Representatives.

American Society of Civil Engineers at Minneapolis

Following the meeting of the American Society of Civil Engineers, at which the development committee report, details of which were given in last week's issue of *Engineering News-Record*, was discussed, members of the society spent four days in visiting engineering works and in various social affairs planned to increase acquaintanceship among the members. At the business meeting, in addition to the development committee discussion, it was announced that the vote taken upon the question of the form in which the list of members should in future be printed resulted in a majority for the plan to consolidate all lists into one. The vote also favored discontinuing the publication of changes of address in the monthly *Proceedings*.

The evening of June 17 was devoted to a reception tendered by the local membership at the Radisson Hotel. Wednesday was entirely given up to an automobile drive around the Twin Cities, with luncheon at the St. Paul Hotel, in St. Paul, and dinner at the St. Paul Town and Country Club, these functions being arranged by the St. Paul Engineers' Society.

Thursday was devoted to an all-day excursion to Lake Minnetonka, which included a two-hour trip on the lake, followed by luncheon at the Lafayette Club. A golf tournament, with prizes donated by the local committee, was held in the afternoon. On Thursday evening Lieut. Col. F. W. Scheidenhelm delivered an illustrated lecture on "The Work of Engineer Troops of the American First Army in France." This was followed by a smoker under the auspices of the Minneapolis Engineers' Club.

On Friday morning the party broke up into small groups for visits to various engineering projects around Minneapolis and St. Paul. At 1.30 p.m. a special train left for Duluth, where the members were received by a large delegation composed of the Duluth Association of Members of the American Society of Civil Engineers and the Duluth Engineers' Club. A steamer was in waiting, and several hours were spent in a cruise about the Duluth-Superior harbor.

At 6.30 a.m. Saturday a special train started from Duluth, via the Duluth, Missabe & Northern Ry., to Hibbing, where the party transferred to flat-cars for a trip down into one of the big open-pit iron mines. Luncheon was served at the Oliver Club, by the courtesy of the Oliver Iron Mining Co., and then, under the auspices of the Engineers' Club of Northern Minnesota, the party went by automobile along the Iron Range 30 miles to Eveleth, thus affording an opportunity to see the development of the Missabe open-pit mines, which produced 60,000,000 tons of ore last year. At Eveleth the special was in waiting to take the party over the Duluth & Iron Range R.R. to the ore-shipping port of Two Harbors, where an inspection was made of the ore docks. The special returned to Duluth at 8.30 p.m., and the party, after a drive around the boulevard on the heights above the city, was entertained at a reception and dance at the Kitchi Gammi Club, the festivities closnig in time to permit the visitors to catch the special leaving at midnight for Minneapolis.

MEMBERS OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS ON FLAT CARS INSPECTING OPEN-PIT IRON MINE AT HIBBING

About three hundred members were in attendance at the meetings and inspection trips in St. Paul and Minneapolis, and probably a hundred more joined the party at Duluth.

Important City Charter Changes in Philadelphia

Notable changes in the charter of the City of Philadelphia have been made in a bill which has passed the Pennsylvania legislature. The old two-chambered council of many members is replaced by a single relatively small council. The councilmen will be paid $5,000 a year. The bureau of health will become a department. There will be a city architect in the mayor's department. To the city-planning commission are given statutory powers.

Street Cleaning and Garbage Changes at Philadelphia

Under the new charter for Philadelphia recently enacted by the legislature, the city will clean its streets and collect and dispose of its garbage, rubbish and ashes, after Dec. 31, 1920,

unless the council by a majority vote, with the approval of the mayor, authorizes the letting of contracts for the work. In the latter event, the present contract restriction of one year is removed. In case a contract for more than four years is made, the city has the option of terminating it at the end of that time or any time subsequently, without damages to the contractor for loss of profits for the unexpired portion of the contract.

Indianapolis Asks Bids on Sewage-Disposal Plant

The board of sanitary commissioners of Indianapolis, Ind., has invited bids for the first of the five sections of the new sewage-disposal plant, and will soon invite bids for the second division. The estimated cost of these are $300,000 and $450,000, respectively, while the total cost of the plant will be about $2,000,000. The first division includes the grit chambers and screens, a 60-in. cast-iron siphon, 1000 ft. long, to pass under the White River, and a 78-in. concrete conduit extending 7700 ft. to the pumping station. The second division will include the buildings for the disposal plant at Sellers farm. For handling the sewage there will be six electrically-driven turbine pumps. Charles H. Hurd is consulting engineer to the board.

Large Dam To Be Built For New York Water-Supply

Contract has been awarded the Hugh Nawn Contracting Co., by the New York City Board of Water Supply, for the construction of Gilboa dam, in Schoharie County, New York, a part of the recent addition to the water-supply of New York City. The dam will divert the Schoharie River from emptying into the Mohawk and divert it to the Ashokan reservoir. It is in two parts, a concrete gravity overfall section 1300 ft. long and 160 ft. total height, and an earth embankment 1000 ft. long. There will be formed a reservoir six miles long with 20,000,000,000-gal. capacity. Quantities are estimated as follows: Excavation, 500,000 cu.yd.; rolled embankment, 500,000 cu.yd.; cement, 480,000 bbl.; masonry, 400,000 cu.yd. The contract price was $6,819,910.

Civil Service Examinations

United States

For United States civil service examinations, listed below, apply to the United States Civil Service Commission, Washington, D. C., or to any local office of the commission, for form 1312.

Assistant designing engineer, Naval Ordnance Plant, South Charleston, W. Va., $9.20 per diem. July 8. File applications before July 8.

Assistant inspector of engineering material (aircraft), $5.92 per diem. July 15. File applications before July 15.

United States.—Chief ship draftsman, U. S. Navy Department, $10 to $12 per diem, draftsman, grade A, $8 to $9.60 per diem; draftsman, grade B, $6 to $7.20 per diem; draftsman, grade C, $5.20 per diem. No date specified. Applications should be filed without delay.

United States.—Chief draftsman, general engineering, architectural, power plant, heating and ventilating, electrical, U. S. Navy Department, $10 to $12 per diem; draftsman, grade B, $6 to $7.20 per diem; draftsman, grade C, $5.20 per diem. No date specified. Applications should be filed without delay.

Valuation engineer, $3600-$4800 per year, and assistant valuation engineer, $2500-$3600 per year; technical staff, income-tax unit, Bureau of Internal Revenue, Treasury Department. No date specified.

Master computer, $2400 to $1800 per year, computer (Grade I) $1800 to $1400 and computer (Grade II) $1400 to $900, Ordnance Department. Applications will be received until further notice.

Engineering Societies

Calendar

Annual Meetings

NEW ENGLAND WATER WORKS ASSOCIATION; Tremont Temple, Boston; Sept. 30, Oct. 1-3, Albany, N. Y.

The Engineering Alumni of the University of Kansas elected the following officers at the fourth annual meeting, held June 16 at Lawrence: President, J. S. Worley; vice-president, W. E. Baldry; secretary-treasurer, George Hood, Kansas University, Lawrence.

The Southern California Association of Members of the American Society of Civil Engineers was addressed June 11 on "Check Dams" by F. H. Olmsted, and on flood-water acts and legislation by Charles E. Haas, the author of the new California conservancy act.

The Cleveland Chapter of the American Association of Engineers elected the following officers at the recent annual meeting: President, F. D. Richards; vice-president, W. P. Blair; secretary, C. M. Williams, and treasurer, A. M. Clark. The chapter is preparing to conduct an investigation of salaries paid technical engineers in Cleveland with a view to working out a schedule of minimum salaries which the county and city will be asked to put into effect.

The Southwestern Society of Engineers, at the recent annual meeting in El Paso, Tex., resolved to organize a publicity committee; to form local sections; to initiate the policy of greater activity in civic affairs; to establish an employment bureau; to make an organized effort to prevent the employment of incompetent men in engineering work, and to approve licensing. It was also resolved that the society is convinced that compensation nearer the modern level of prices is required to retain the services of the best technical men. The board of directors recommended a plan to charter the society as a district of the American Association of Engineers, provided that all of the members of the society go into the association in a body.

The New York Chapter of the American Association of Engineers held a meeting June 25 at which the following papers were presented: "Railroad Engineering," by R. S. Parsons, chief engineer, Erie R. R.; "Highway Engineering," by W. G. Thompson, state highway engineer of New Jersey, and "The Work of the Engineer at the Front with a Combat Division," illustrated, by Col. F. A. Snyder, 103rd United States Engineers.

The Portland Chapter of the American Association of Engineers has effected a permanent organization, with the following officers: President, W. H. Marsh; vice-presidents, A. H. McKeen, T. W. Saul and O. Laurgaard; secretary, R. W. Barnes and treasurer, C. F. Thomas. Tentative plans have been drawn for amalgamation with the Oregon Society of Engineers. They are under consideration by the national board of the American Association of Engineers.

The Engineers' Club of Minneapolis and the Twin City Chapter of the American Association of Engineers have formed a joint engineering committee to assist in the solution of the engineering problems arising in connection with the settlement of the street-railway franchise. F. K. Bennett is chairman of the committee.

The Engineers' Club of Trenton, N. J. gave a reception June 17 to Trenton men who have returned from overseas duty with the engineers.

Personal Notes

R. T. Betts, for the past five years deputy chief engineer, Department of Docks, New York City, has resigned to become chief engineer, Robbins-Ripley Co., Inc., 50 Church St., New York City. Mr. Betts has been in the service of the Department of Docks for the past 22 years. He was previously in the Bureau of the Wallabout Improvement, Department of City Work, of Brooklyn, and in water-supply work for the City of Brooklyn. He was graduated from the School of Mines, Columbia College, in 1890.

Capt. Walter S. Ingalls, U. S. A., who recently returned from France and received his discharge from the service, has been appointed adjutant

general of the State of Arizona. For a number of years previous to his war service he was an engineer in the office of the surveyor general of the state. He is a veteran of the Spanish-American War and has been connected for some time with the Arizona National Guard.

CHARLES C. COOK, has resigned as city engineer of Wheeling, W. Va., after 16 years of service.

HARRY W. BOETZKES, formerly in irrigation, highway and contracting work in the Northwest, with headquarters in Seattle, and since 1917 captain with United States Engineers in France and the Balkan States, has returned, demobilized, with the Roumanian Bridge Commission, and in that connection will make his headquarters in New York City.

CAPT. HARRY TUCKER, Engineers, U. S. A., who recently returned from France and received his discharge from the service, has been appointed associate professor of highway engineering, State College of North Carolina, and becomes acting head of the new department of highway engineering, which has just been created as a subdivision of the civil engineering department.

JAMES E. SELLERS, formerly of San Diego, Calif., and Phoenix, Ariz., has returned to the States after serving for 18 months with the 23rd Engineers. Mr. Sellers was one of the organizers of the Society of the 23rd Engineers, now having a membership of nearly 4000. He will return to Phoenix and resume his engineering practice.

MAJ. ERIC KEBBON, Engineers, U. S. A., who recently received his discharge from the service, has become associated with Welles Bosworth in the practice of architecture, with offices at 527 Fifth Ave., New York City.

WILLIAM MCGIBBON, previously of the State Highway Commission of Iowa, has been appointed county engineer with headquarters at Knoxville, Iowa, succeeding W. O. PRICE, who has been appointed district engineer, with headquarters at Chariton, as noted elsewhere.

W. SYDNEY WAGNER and ROBERT R. HOUSTON have been admitted to partnership with William S. Post and J. Otis Post in the firm of GEORGE B. POST & SONS, architects, New York City and Cleveland. The business is to be continued under the present firm name.

LIEUT. JOHN A. FULKMAN, Sanitary Corps, U. S. A., has received his discharge from the service and has resumed his former work as assistant engineer, MORRIS KNOWLES, INC., engineers, Pittsburgh.

LLEWELLYN N. EDWARDS, supervising engineer of bridges, Department of Works, Toronto, Ont., has resigned to become senior highway bridge engineer, United States Bureau of Public Roads, Washington, D. C. He was graduated from the University of Maine in 1898 and engaged in bridge-engineering work. In 1905 he became designer and estimator, office of the bridge engineer, Boston & Maine R.R., and later engaged in similar work for the Chicago & Northwestern Ry. In 1907 he was appointed structural engineer, Grand Trunk Ry. In 1913 he joined the engineering staff of the City of Toronto.

H. A. SEWELL, formerly county engineer, Pend O'Reille County, Washington, has been appointed engineer, Panhandle Highway District of Idaho, with headquarters at Spirit Lake.

JULIUS K. MUNROE, previously of the engineering department, Morgantown & Kingwood Ry., has been appointed state road commissioner of West Virginia, with headquarters at Charleston, succeeding T. S. SCANLON, resigned.

H. G. CLARK, chief engineer, Chicago, Rock Island & Pacific R.R. previous to the recent return of C. A. Morse, has been appointed assistant to the Federal manager, succeeding H. M. SLOANE, resigned to become assistant to the president, Chicago, Milwaukee & St. Paul R.R., as noted elsewhere.

LIEUT. WILLIAM L. STANTON, Engineers, U. S. A., who recently returned from France, has been discharged from the service and is now in the office of the city engineer, Flint, Mich.

I. J. EIDMAN, assistant bridge engineer, Kansas State Highway Commission, has been appointed bridge engineer, South Western Engineering Co., Hutchinson, Kans.

H. M. SLOANE, assistant to the Federal manager, Chicago, Rock Island & Pacific R.R., has resigned to become assistant to the president, Chicago, Milwaukee & St. Paul Railroad.

HARRY S. MARSHALL, has resigned as chief engineer, A. J. Yawger & Co., general contractors, Indianapolis, to become chief engineer in charge of construction, F. K. Vaughn Building Co., Hamilton, Ohio.

LIEUT. HENRY J. HORN, Sanitary Corps, U. S. A., recently returned from France, has received his discharge from the service and has resumed his former work with GANNETT, SEELYE & FLEMING, engineers, Harrisburg, Penn.

R. E. BURGER has resigned as president and general manager of the Richland Public Service Co., of Ohio, to become chief engineer of Henry L. Doherty & Co., public utility operators, New York City.

MAJ. THERON M. RIPLEY, U. S. A., has received his discharge from the service and will return to his duties as division engineer, Division No. 3, State Highway Department of New York, with headquarters at Watertown.

H. A. MARSHALL, acting road engineer, Kansas State Highway Commission, has been appointed chief engineer, South Western Engineering Co., Hutchinson, Kans.

LIEUT. H. E. MILLER, Construction Division, U. S. A., who was recently discharged from the service, has been appointed director of the bureau of engineering and inspection, North Carolina State Board of Health, with headquarters in Raleigh.

HARRY CONRAD, of the firm of COULTER & CONRAD, engineers, Wheeling, W. Va., has been appointed city engineer of Wheeling, succeeding CHARLES C. COOK, resigned.

FRED OLDER, Adrian, Mich., has been appointed city engineer of Ypsilanti, Mich., succeeding W. R. CALDWELL, resigned to become chief engineer of the Palma Construction Co., Ypsilanti, as noted elsewhere.

GEARY KIMBALL, CHARLES SEMPER and C. W. CROSS have been assigned as highway engineers to the Ogden, Utah, branch of District No. 2, United States Bureau of Public Roads.

W. R. CALDWELL has resigned as city engineer of Ypsilanti, Mich., to become chief engineer of the Palma Construction Co., highway contractors, of Ypsilanti.

LIEUT. CHARLES BOYCE, U. S. A., has received his discharge from the service and will report to the American Red Cross at Washington, D. C., to become sanitary engineer.

W. O. PRICE, county engineer, Knoxville, Iowa, has been appointed district engineer, with headquarters at Chariton.

J. F. WITT has resigned as county engineer of Dallas County, Texas, in which position he has served since 1907.

FRED W. SIMONS, city engineer of Rahway, N. J., has been appointed city manager of Elizabeth, N. C.

D. E. GILMER, of Hutchinson, Kans., has been appointed superintendent of construction, Federal-aid roads, Reno County.

FRED HOFFMAN, contractor and engineer of Long Beach, Calif., has been appointed city engineer.

A. R. TOWSE has been elected county engineer of Pensacola, Fla.

OBITUARY

ERWIN F. PAYNE, head of the E. F. Payne Paving & Contracting Co., Cleveland, died recently in that city. He had been at the head of the company for the past 40 years and was actively engaged in the business until his retirement two years ago.

FRANK C. LAMARCHE, general superintendent, South Chicago Shipbuilding Co., died recently in Chicago. He was previously general superintendent of the American Shipbuilding Co., of Cleveland.

West Coast Lumbermen To Hold Annual Meeting

The West Coast Lumbermen's Association announces that it will hold its annual midsummer meeting at Paradise Inn, Mount Rainier National Park, July 30-31. It is expected that lumbermen from both Oregon and Washington, with their families, will attend the convention in large numbers.

A report will be made by Axel Oxholm, who has just returned from the Scandinavian countries, where he studied lumber trade conditions for the United States Department of Commerce. Other speakers will be C. E. Paul, consulting engineer for the National Lumber Manufacturers' Association; Chester J. Hogue, in charge of the West Coast Association's New York office, and L. C. Boyle, attorney for the national organization.

Asphalt Association Announces Increase in Staff

Several additions to its organization have been announced by the Asphalt Association, recently formed, as reported in *Engineering News-Record* of June 19, 1919, p. 1237. The research and testing department of the association is headed by Prevost Hubbard, formerly chief of the research and testing division of the Bureau of Public Roads.

Several field engineers have also been appointed; Fred W. Sarr, formerly second deputy highway commissioner of New York; A. T. Rhodes, who was for several years street commissioner of Worcester, Mass., and, more recently, secretary of the Granite Block Manufacturers' Association, will have charge of the New England territory and other Eastern points; and J. B. Hittell, formerly city engineer of Chicago, who will have charge of the association's work in the Middle Western States. No representative for the district to be controlled from the Atlanta, Ga., office has been named.

Canadian Industrial Congress To Be Held at Calgary

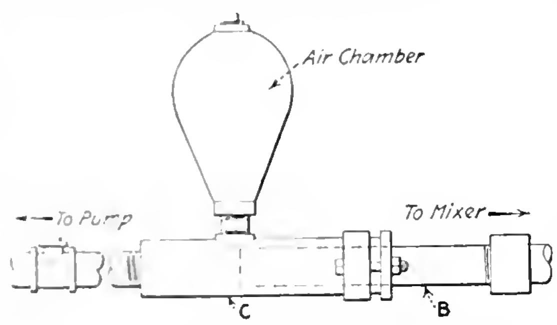
Western Canada is to have an industrial congress which will meet at Calgary, Alta., Aug. 13-14, and will then take a trip through the territory, including other Western Canadian cities. Among the places to be visited will be Medicine Hat, Alberta and Edmonton. The congress will be educational to a large extent, and along industrial lines.

Some of the subjects for discussion are: "Western Markets," "Western Industry," "Pacific Trade and Transportation Routes," "Oriental Commerce," "Future Alignment of Manufacturing, Considered with Reference to the East and West," and the question of building up the Pacific region and adjacent inland territories. Congress headquarters have been opened at the Palliser Hotel, Calgary, Canada, under the manager, John M. McGreevy. Further information may be obtained there.

Expansion-Joint Air Chamber for Roadbuilders' Pipe Lines

A combined expansion joint and air chamber to prevent water hammer, for pipe lines laid above ground in roadbuilding and other work, is shown in the accompanying illustration. It is claimed that this joint will overcome all the difficulties due to contraction and expansion of pipes which throws them out of line, while the air chamber prevents trouble with water hammer which often breaks pipe and mixer hose when the water is shut off suddenly.

One of these expansion joints is recommended for every 800 to 1000 ft. of



PIPE LINE EXPANSION JOINT AND AIR CHAMBER

pipe. While the combination joint and air chamber can be supplied, it is not necessary to use the air chamber on every joint. Its use upon about every third joint is said to be sufficient.

The expansion joint, which allows for 12 in. of expansion or contraction, is formed by having a brass pipe B, which telescopes into the casing C through a gland or stuffing box. The pipe line is connected to each end of the combination, which thus becomes a part of the line.

The combination described is manufactured by the C. H. and E. Mfg. Co., of 384 Clinton St., Milwaukee, Wis.

Business Notes

THE OSHKOSH MFG. CO., manufacturer of contractors' machinery and equipment, of Oshkosh, Wis., has reported the appointment of Ross Hunter as Eastern sales manager. Mr. Hunter has had long experience in the machinery selling field, his territory covering the entire country. His offices will be at 154 W. 38th St., New York City, where a complete line of Oshkosh contracting machinery will be kept in stock.

THE MACON CONCRETE ROLLER CO., of Macon, Ga., has been formed to manufacture concrete paving rollers by a process patented by W. L. Ashmore and W. T. Morgan, Jr.

THE C. J. CARTER LUMBER CO., of Kansas City, Mo., THE DONIPHAN LUMBER CO., of Kensett, Ark., and THE MARSH AND TRUMAN LUMBER CO., of Chicago, which are all manufacturing and selling interests of Bloxonend flooring, give notice that they have been merged into a single corporation, to be known as the CARTER BLOXONEND FLOORING CO., with home office in Kansas City. The sales office will be located at 1601 McCormick Bldg., Chicago, Ill. The individual lumber business of each of these firms will be continued under the old names as heretofore. C. J. Carter, the president, will have charge of the Kansas City office, while M. G. Truman, the vice-president, will be in charge of the Chicago office.

THE MCGRAW-HILL CO., INC., of 10th Ave. at 36th St., New York City, reports the removal of the Western office of *Chemical and Metallurgical Engineering* and *Engineering and Mining Journal* from the Newhouse Bldg., Salt Lake City, Utah, to the Rialto Bldg., San Francisco, Calif.

THE AUSTIN CO., of Cleveland, Ohio, announces that O. D. Conover, formerly vice-president and chief engineer of the C. W. Price Engineering Co., of New York and Chicago, and production manager of the Ludlum Electric Furnace Co., has resigned the latter position to become associated as production and sales engineer on foundries and steel plants for the Austin Co. Mr. Conover has had experience as engineer in charge of the design and construction of a large number of steel plants, foundaries, electric furnaces, and other equipment, both in this country and abroad.

THE SULLIVAN MACHINERY CO. has established a branch office at Room 810 Park Bldg., Cleveland, Ohio, under the management of Ralph T. Stone, formerly sales engineer in the New York office.

Trade Publications

The following companies have issued trade publications:

THE HOLT MANUFACTURING CO., of Peoria, Ill.; bulletin, 9 x 12 in., 16 pages, illustrated; describes the various standard sizes of Caterpillar tractors.

THE TRAILMOBILE CO., of 571 East Fifth St., Cincinnati, Ohio; catalog 7 x 9 in., 31 pages, illustrated, and three folders 8½ x 11 in., illustrated; describe various forms of trailers manufactured by the company.

THE AMERICAN MANGANESE BRONZE CO., of Holmesburg, Philadelphia, Penn.; catalog, illustrated; contains descriptive matter and illustrations of hydraulic castings, gear wheels, propellers, ingots, valves, bronze forgings, etc. The title of the catalog is "High-Grade Bronzes for Engineering Purposes."

THE TIDEWATER OIL CO., of 11 Broadway, New York City; catalog, 6 x 9 in., 46 pages, illustrated; describes the uses, economy and efficiency of fuel oil and the apparatus necessary for its use.
